Abstract

Introduction: When designing new hospital construction or refurbishment can be adopted green practices both in design and in construction and operation.

Objective: To explore the ecological awareness and behavior of nursing staff in a dialysis unit.

Methods: This survey involved 90 Registered Nurses and Nurses' aides of General Hospitals in the Capital (Athens) and in province of Greece (Region of Peloponnese). These individuals were given an overall anonymous self-completed questionnaire.

Results: The most important finding is that 70.8% considered as mandatory an organized effort to protect the environment in their workplace. Nurses think that greater environmental awareness is obtained 37.1% by using guidelines, 23.6% with relative stimulation, and 20.2% with educational lectures, 10.1% using poster and 6.7% in view educational videos. Finally, the correlations of ecological awareness with demographic characteristics of the sample revealed that older nursing staff with more years of working experience knows about environmental management ($p\text{-value}=0.012$). At the same time, gender ($p\text{-value}=0.030$) and educational level of the nursing staff plays an important role in the knowledge of it ($p\text{-value}=0.044$).

Conclusions: To control costs and environmental pollution guidelines for saving energy and water and the use of environmentally friendly materials should be implemented. Thus, hospitals can become more competitive by reducing the amount of natural resources used.

Keywords: awareness, behavior, ecological, Green Hospitals, hemodialysis.

1 Introduction

According to International Council of Nurses the complexity and need for environmental protection and energy sources causes each professional group to actively participate in every effort to preserve the environment, aiming at saving resources [1]. Worldwide, hospitals and all health care facilities try to provide personalized, modern and high quality care, without burdening the natural environment. Global warming, climate change and the effort to adopt environmentally friendly habits are global issues from the late 20th century. In recent years, global organizations and legislative authorities at national and European level have been more sensitive to adopt rules for the protection of the environment, such as energy conservation, waste management, and safe management of pharmaceuticals.

Hospitals and all health organizations should be role models for their staff, patients, attendants and the general population. In these places more energy and water are consumed and much waste is produced compared to industries. Guidelines for saving energy and water and the use of environmentally friendly materials should be implemented to control costs and environmental pollution. In this paper an attempt is made to present good practice in Greece, and issues related to waste management in Dialysis Units are presented according to Greek and foreign countries' experience.

In countries such as the USA, knowledge how to build ecological healthcare organizations is developed in a satisfactory level. In addition, there are programs such as the "Green Code of Health and Hospitals for a Healthy Environment" that provide guidance and tools for the creation of green-offices services have supervision of hospital construction. The

green service not only ensures the "health of buildings", but also contributes to the health of the local and global community. The backbone that a green office has is the control and proper operation of cooling and heating systems and energy saving matters [2, 3].

Mercury is a highly toxic metal that is harmful to the environment because of its long-term uncontrolled free disposal. Its deposition to the soil leads to its transfer in food chain. Even the smallest exposure to mercury, is associated with central nervous system damage, kidney and liver failure, abnormal reproductive system and fetal development, learning difficulties. The mercurial sphygmomanometers, containing 80-100g, is still used in European hospitals and private clinics. For this reason, a source of mercury, about 7-17 tons, is free into the environment and pose a health risk [4,5]. However, these devices should substituted by digital sphygmomanometers that do not contain mercury. The European Commission Directive 2007/51EC prohibited the use of this type of instrument in April 2009 [6, 7, and 8].

Many hospitals are reviewing the use of medical products made from PVC or vinyl because of potential harm to patients and the potential impacts on environmental health [9, 10]. The use of flexible PVC medical devices exposes patients to the toxic substance (DEHP) during blood transfusion, the administration of fluids or parenteral nutrition with special bags, lines of hemodialysis or peritoneal dialysis, urine drainage bags, drains, oxygen masks, tracheal tubes, ambu, aspiration catheters or levin. When removed as waste PVC leads to dioxin exposure, a known human carcinogen substance that also causes abnormalities in the reproductive system and fetal development. We recommend using devices from silicon, polyethylene, polyurethane during interventions in male neonates, pregnant with male babies or teenage boys [11, 12, and 13].

The main source of dioxin in healthcare environments is the "traditional" burning of hospital waste. Products containing bleach and burned in blast, including medical devices and derivatives make dioxins [14].

Patients, staff and visitors at hospitals and clinics are at risk of developing asthma episodes. Given that hospitals are places of healing it is surprising that during patients' stay these individuals are exposed to health risks. The literature has shown that there are some factors in places providing health care that can cause asthma or asthma attacks. One of the main factors causing asthma is tobacco smoke. For this reason, smoking is banned in all public places since June of 2009. However, biological and chemical agents, such as chemicals for cleaning and disinfecting surfaces and instruments, chemicals for the construction of buildings and furniture production, latex gloves and medications are associated with asthma [15].

Stopping or reducing the use of chemical cleaning using mop and duster microfiber reduces the use of chemical cleaners in many places. These products are made from special fibers that trap dirt without the use of chemicals. Careful planning of cleanliness is important. The use of chemicals can be reduced by cleaning surfaces on a daily basis and not more often. The use of a milder cleaner for general cleaning on a regular basis and a strong cleaner only when necessary is possible to reduce exposure to risk factors. Prevention can help to reduce the chemicals. For example the use of specific carpet in the entrance of each clinic or room prevents the soil and reduces the frequency of cleaning. Replacement of latex gloves with latex-free gloves produced from nitrile rubber, neoprene or other material [11].

The construction and use of buildings in all sectors consume 3 billion tons of raw materials annually (40% of rough stone, gravel, sand, and steel, 25% of virgin wood, 40% of its energy resources, 75 % of PVC, 17% of freshwater flows) and causes significant waste (25-40% of municipal solid waste and construction and demolition waste only), 50% of CFCs, approximately 30% of production is CO₂, and significant toxic emissions. Given this, the opportunities are important for improving the quality of the environment through eco-planning, design, construction, operation and maintenance practices. Improving the environment through green building practices is consistent with the recent voluntary agreement of the American Hospital Association in the United States and the Environmental Protection Agency to reduce waste and toxicity. The building design and construction practices can be configured for the protection of health [16, 17, and 18].

Environmentally Friendly Hospitals: Two hospitals in Michigan are green, the Cancer Center of Santa Maria and the Boulder Community Hospital. The Cancer Center offers a rooftop garden that helps insulate the building and reduce water runoff. They also use the remaining steam from the heating system to melt snow sidewalks, reducing costs. The Boulder Community Hospital has painted the ceiling in white to reflect the heat of the summer and consequently reduces air conditioning demand. Regarding the cost of construction of these hospitals burdened the budget by 3%. Hospital facilities that adopt environmentally friendly practices can save money help the environment and to minimize health risks from toxic substances [19, 20, and 21].

Ecological Hospitals: The prevention and treatment of disease in combination with health promotion has been the cornerstone of creating hospitals. Health is linked to the environment; it seems that any change in the environment has a direct impact on health [22]. The hospitals are a social microcosm using a variety of products, offer services, and generate a large number of waste that if not properly managed affects both health and the environment deleteriously. Health professionals are invited to defend public health in situations where water scarcity, air pollution and toxic products are flooding the environment and threaten public health. There is therefore an imperative need for hospitals to make their services safer, healthier and more environmentally friendly [2, 22]. A simple but essential step in this direction is the creation of "green" hospitals. The creation of green hospitals is feasible with strategies in respect to the development-creating sustainable buildings, the acquisition of environmental awareness and the use of environmentally

friendly materials and consumables in the care of patients [22, 23, and 24]. Furthermore, climate change is one of the challenges of this century and has been recognized as a health priority [25].

The purpose of this study was to investigate the attitudes, perceptions and behaviors of nurses in Dialysis Unit regarding the existence of an ecological awareness, and their association with factors such as gender, age, educational profile, occupational status, working experience, and years of service

2 Materials and methods

2.1 Sample

The sample of the study was 90 Renal Nurses who worked in Dialysis Units in General hospitals in the Greek capital city and the region. The preconditions for the participation in the study were the following:

- 1) Adults (over 18 years)
- 2) Attaining at least a secondary educational level education.
- 3) The consent to participate in this study.
- 4) The questionnaires will be completed by the same people who participated in the survey.
- 5) The population under study was informed about the purpose and the privacy and anonymity of the process was guaranteed.

2.2 Procedure

The researcher provided the questionnaires with an envelope within which the person would deliver closed (in person) after completing the questionnaire in order to preserve confidentiality. Researchers were available to people who wanted to ask pose questions.

2.3 Questionnaire

Individuals in the sample were given a total anonymous self-administered questionnaire designed for the purpose of the study that captures basic demographic characteristics and includes questions related to socio-demographic data (marital status, children, education level, employment status) and their identity (gender and age). Also, they were asked to answer questions related to years of service, professional experience and questions concerning the protection of the environment and in particular the system of environmental management; toxic management, water consumption, disposal of waste in Dialysis Unit. We also used some questions from the questionnaire "Go Green Dialysis" which EDTNA/ERCA used for pre-project survey, after written permission.

2.4 Ethics

This research has responded to the fundamental ethical principles governing the conduct of research. Specifically:

- 1) Complete discretion as to the information concerning the examinees was safeguarded.
- 2) Anonymity was guaranteed.
- 3) The results were used solely for the purposes of the research and only by this research group.
- 4) The reliability of the results ensured the accurate and complete description of the methods, the sample material and the general conditions of the survey.

2.5 Data analysis

A comparison of the responses of nursing staff between hospitals and demographic characteristics and questions on environmental protection and the development of ecological awareness was done. For these purposes the following statistical tests: the χ^2 test and the parametric comparison of more than 2 average price variance analysis in one direction (one-way ANOVA) were applied. The p-value based on two-tailed tests. The p-value with a value lower than 0.05 was considered as statistically significant. To perform the statistical analysis the software SPSS 18 was used.

3 Results

Table 1 show that 19.1% of participants are male and the remaining 80.9% female. With regard to marital status, 25.6% of people are not married, 65.6% married, and 7.8% and 1.0% are divorced or widowed, respectively. 74.4% are Technological institution graduates, 4.4% are graduates of higher education (universities) and 14.4% secondary education. 6.8% has an additional postgraduate diploma qualification, while none has a doctorate. Referring to the nationality, the whole sample is Greek. 10.7% are located in Argolis, 27.4% in Athens, 14.3% in Kalamata, 10.7% in Korinthos, 15.5% in Tripoli, 16.7% in Sparta and the remaining 4.8% in Molai. Regarding the professional status, 7.8% of participants are head nurses. These descriptive statistics are presented in detail in Table 1.

Table 1: Demographic characteristics of the sample

Demographics	n	(%)
Sex		
Woman	72	80.9
Man	17	19.1
Marital status		
Single	23	25.6
Married	59	65.6

Contract staff	9	10.5
Position		
Head nurse	7	7.8
Nurse	82	92.2

The average age of nurses was 38.4 years with a minimum age of 24 years and maximum of 49 years. The variable of age appeared to follow a normal distribution (symmetrical). Still, the 48 (53.3%) of participants in the study had an average of 2 children. Finally, mean time of working experience was 13.5 years ranging from 0 to 29 years.

In Table 2 it is observed that 81.7% of respondents indicated that the nursing staff of Dialysis Unit can help protect the environment. According to the responses of nurses, 35.2% said that they believed that the volume of hospital waste could be limited, 31.8% believe that electricity consumption could be limited as well as water consumption 20.5% said that water consumption. The 37.1% of the respondents believe that their colleagues may be influenced to gain increased environmental awareness using guidelines using 20.2% educational lectures, 10.1% using posters and 6.7% with view educational videos, 23.6% with relative motivation. Still, 70.8% considered mandatory the support of an organized effort to protect the environment in their workplace, while 28.1% would support it if they had free time.

Table 2: Attitudes, perceptions and behaviors of nurses regarding the protection of the environment and the motivation for development of ecological consciousness.

Questions	N	(%)
Do you think the Nursing Staff in Dialysis Units can help protect the environment?		
No	2	2.3
Yes	71	81.7
Maybe	14	16.1
In your opinion which of the following has a greater potential of reducing?		
Water consumption	18	20.5
Electricity power consumption	28	31.8
Hospital waste	31	35.2
Gas or oil consumption	11	12.5
How do you think you can influence your colleagues to gain increased ecological awareness?		
Posters	9	10.1
Training video	6	6.7
Speeches	18	20.2
Guidelines	33	37.1
Motivation	21	23.6
Other	2	2.3
Would you support an organized effort to protect the environment in your workplace?		
Yes, I think it compulsive	63	70.8
Yes, if I had free time	25	28.1
No, I would not support it	1	1.1

About environmental management, 55.8% of the sample responded that they have knowledge about the existence of a relevant law for the protection of the environment. The 43.1% of nurses said that "maybe" the hospital is implementing a program of environmental management. 51.1% responded that the hospital has an employee responsible for environmental management of hospital waste, energy, pollution, health and safety. 40.5% of the sample responded that they don't know what departments or individual services of Hospital consume hazardous or toxic agents. Also, according to 70.8% of the nursing staff personal protective equipment that are required for the handling of hazardous or toxic agents are readily available to staff.

There is a statistically significant correlation between sex and existence of place of incineration or landfill ($\chi^2= 8.665$, $p\text{-value}=0.013$). 23.5% of men are not sure if medical instruments with mercury are used in the unit ($\chi^2= 7.002$, $p\text{-value}=0.030$). 66.7% with two year of education are found to be positive that there is a system of environmental management of the waste of their unit (Fisher's exact test $p\text{-value}=0.044$). Age and working experience are also to have statistically significant correlation with characteristics of waste management in the Dialysis Unit as it shown in Table 3.

4 Discussion

Protecting the environment is extremely important for health, wellness and life itself. According to the International Council of Nurses (1986) the complexity and necessity of environmental protection causes each professional group to actively participate in every effort to preserve the environment [1]. Worldwide, hospitals and all health care facilities provide personalized, modern and high quality care. Global warming, climate change and the effort to adopt environmentally friendly habits are global issues from the late 20th century. In recent years, global organizations and legislative authorities at national and European level have been sensitized to adopt rules for the protection of the environment, such as energy conservation, waste management, and safe management of pharmaceuticals. Hospitals and all health service organizations should be role models for their staff, patients, attendants and the general population. In these areas the consumed energy, water, and waste produced are more than what the industries produce [26-28]. To control costs and environmental pollution guidelines for saving energy and water and the use of environmentally friendly materials should be implemented. Thus, hospitals can become more competitive by reducing the amount of natural resources used.

In this survey 90 people constituted the total sample of the study in order to investigate ecological awareness and performance of nursing personnel in a dialysis unit. To achieve this aim, participants were given a comprehensive questionnaire which reflects the opinions, attitudes and beliefs related to environmental protection and the development of ecological awareness. The descriptive results from this study showed that the largest proportion of the sample believes that the Nursing Staff of Dialysis Unit can help protect the environment. In this direction, the volume of

infectious waste seems to appear as the dominant power limitation. Moreover, the most popular way to motivate colleagues is to gain increased ecological awareness. An important finding is the fact that the vast majority feels obligatory to support any organized effort to protect the environment.

Finally, the correlations of ecological awareness with demographic characteristics of the sample revealed that older nursing staff with more years of working experience knows about environmental management. At the same time, gender and educational level of the nursing staff plays an important role in the knowledge of it. In conclusion, therefore, this study determined of the characteristics of nurses that affect the attitude toward the environment, and reflect the perceptions and attitudes about the development of ecological consciousness. So focusing on these elements, it is possible that this study can contribute substantially to raising Nurses in ecology. The ultimate goal is to reduce environmental pollution and creating "green" hospitals. In this way, hospitals will be friendlier to the environment, control costs and reduce waste of public money, and will work in favor of public health [1, 29-30].

A similar research study «Go Green in Dialysis» (Ecological approach Dialysis) prepared by EDTNA / ERCA (European Association of Nurses for Dialysis and Transplantation) and the company Fresenius Medical Care in 2010 [31]. That survey involved 872 people from 39 different countries and concluded also that:

Nurses in the Dialysis Unit can help to protect the environment. Low priority factor for nephrology units is the consumption of oil or natural gas. They also believed that the best way to improve colleagues'

Environmental consciousness is educational seminars. The present study also conclude that nurses believe that their colleagues could be influenced to gain increased environmental awareness using guidelines, with relative motivation, and with educational lectures, using posters and educational videos.

Energy saving saves money and helps hospitals to become competitive. The parts of the hospital that consume large amounts of energy must be recognized in order to investigate the possibility of reducing energy consumption. The recirculation of the air, the adjustment of temperature depending on the department and the improvement the insulation of the building can reduce hospitals heating and cooling needs [32]. The environmental management should include objectives, timetable and persons responsible for the adoption of recycling and responsible waste management. An environmental management system, however, requires the support and involvement of all levels of workers. Staff training, reporting and presentation of successes increase their enthusiasm and contribute to the success of the management system. Instructions should be written for handling, storage and disposal of dialysis unit waste.

The cost of a hospital for lighting can be reduced by replacing ordinary light bulbs with energy saving bulbs, reducing lighting sources, installing motion detectors and installing larger windows to use natural light. The solar collectors can reduce the energy or fuel used. Wind turbines and geothermal energy accumulators are potential sources of energy to run a hospital

5 Conclusion

When designing new hospital construction or refurbishment can be adopted green practices both in design and in construction and operation. Thus, can be used:

- 1) For heating: Solar batteries, thermostats temperature decline, reducing the room temperature at night, hot water collection tanks, small boiler in order to insulate the pipes, boilers and tanks.
- 2) For electricity: modern lighting elements, night lighting, motion detectors, appliances energy class A.
- 3) For air conditioning should estimate the parameters of each clinic, placed thermostats, insulated pipes, reducing the flow of air in empty rooms or workplaces, recirculation of cold air batteries for photovoltaic energy production, planting and placement of plants to reduce uptake of solar and wind blocking, positioning obscuration films on windows to reduce heat loss.

Nurses should and can adopt ecological attitude and behavior, both in the workplace and in the community. This is done with the following proposed ways: avoid any direct contact with mercury, information on mercury levels and implementation of international guidelines, fewer thermometers and sphygmomanometers, proper removal of those containing mercury according to international regulations, dental use of substances that do not contain mercury, use of materials, latex-free and PVC (floor, wall paints, carpets, roof lining, piping), using wood products without formaldehyde, chromium or arsenic, use materials manufactured without ozone depletion, recyclable metal and cement, training of staff, measurement of energy and water consumption, greenhouse gas emissions, waste, adopting recycling programs.
