**Abstract**

Many strains of *E. coli* have been identified as food borne pathogens inducing serious gastrointestinal diseases and even causing death in humans. Amongst these are those referred to as Shiga or Vero toxin producing *E. coli*. Bobozi is an Indigenous Nigerian ready to eat snack food made from cassava and is widely consumed in most parts of the country. The objective of this study was to Isolate and Identify *E. coli* from Bobozi, analyze their Shiga toxin (stx) gene profile and thereafter determine their verotoxin capabilities. A total of 248 samples of Bobozi were purchased from hawkers in the metropolis of Benin City, Edo state, Nigeria. Isolation and Identification was done using standard microbiological methods. Analysis for the presence of Shiga toxin (stx1 and stx2) genes was done using PCR technique and for their verotoxigenic potentials using tissue culture assay on Vero cells. Result of the investigation reveals that of the total 248 samples collected, 107(43.15%) had *E. coli* isolated from them. Total number of *E. coli* isolated from the 107 samples was 386. Shiga toxin gene analysis of the isolates reveal that 169(43.78%) had stx1 gene alone, 112 (29.02%) had stx2 gene alone, 3(0.78%) had both stx 1 and stx 2 genes while 102 (26.42%) had none of the two genes. Tissue culture assay on Vero cells indicate that there is a strong relationship between the presence of stx genes and their degree of cytotoxic effect on vero cells as over 80% isolates without the genes exhibited weak cytotoxic effect whereas over 80% of those with the genes exhibited more than strong cytotoxic effect.

**Keywords**: Bobozi; Verotoxins; Escherichia coli; Shiga toxins; Vero cells.

**1. Introduction**

*Escherichia coli* although are the predominant non-pathogenic facultative flora of the human intestine, some strains are known to have developed the ability to cause disease of the gastrointestinal tract and have been identified as a leading cause of food borne illness all over the world (Hussein, 2007). Amongst these are those referred to as Shiga or Vero toxin producing *E. coli*. Although most of the reported human illness outbreaks associated with shiga toxin producing *E. coli* have been attributed to the 0157:H7 serotype, reports however indicate that other *E. coli* serotypes implicated in food borne outbreaks associated with shiga toxin producing *E. coli* have been isolated from the 0157:H7 possess these genes (ECDC, 2011; Beutin, et al., 2004; Bennett and Bettelheim, 2002).

Bobozi is an Indigenous Nigerian ready to eat fermented snack food made from cassava and is widely consumed in most parts of the country. They are mostly prepared, stored and sold under conditions that can be said to be hygienic. They are either displayed in open trays in the market or hawked along the street and major highways. Contamination with organisms such as *E. coli* can therefore not be ruled out. Consequent upon the above, this work was done to Isolate and identify *E. coli* from Bobozi, analyse their vero toxin (stx) gene profile and determine their verotoxigenic potentials on vero cells.

**2. Materials and methods**

**2.1. Isolation and identification of *E. coli***

A total of 248 samples of fermented cassava chips (Bobozi) purchased from hawkers in the metropolis of Benin City, Edo state, Nigeria, were mashed in sterile mortar and 1g homogenized in 9ml buffered peptone water. Serial dilutions of up to 10⁻⁵ were then made and 1 ml of each homogenate was then plated on Eosin methylene blue (EMB) agar and incubated at 37°C for 24 h. Pure cultures of all colonies exhibiting typical dark to purple colonies with metallic sheen which is characteristic of *E. coli* on EMB were then made in readiness for biochemical tests. Biochemical tests to confirm *E. coli* was done using the API 20E test strips and in accordance with the method described by Holt et al. (1994).

**2.2. Screening for shiga toxin (stx 1 and 2)**

Analysis for the presence of Shiga toxin (stx1 and stx2) genes was done using PCR technique with primers manufactured by Premedesign Ltd, UK, targeting the stx1 and stx2 genes according to method outlined by Blanco et al. (2003). DNA extraction was done according to Sambrook and Russell, (2001). The mixture for the amplification of stx1 and stx2 genes consisted of 2.5 µl of PCR buffer (10mM Tris–HCl pH 9, 50mM KCl, and 0.1% Triton X-100), 2.5mM MgCl₂, 0.2mM of each dNTP, 1µM of each primer and 1.25U of Taq polymerase, in a final volume of 25µl. Amplifi-
cation was done with a 96 well dual head Pelter thermocycler (DNA engine) model PTC-200. The amplification conditions consisted of an initial denaturation step at 94°C for 4 min, and 30 cycles of 94°C for 1 min (denaturation), 55°C for 1 min (annealing), and 72°C for 1 min (extension), and a final step at 72°C for 10 min. PCR products were analyzed by electrophoresis on 1% agarose gel and visualized by ethidium bromide staining in a UV trans-illuminator.

2.3. Tissue culture assay for verotoxin production

Preparation of extract for tissue culture assay was done by first inoculating pure cultures of all test isolates maintained on nutrient agar slants in 5ml Trypticase soy broth (TSB) and incubated overnight at 37°C. 500µl of the inoculated Trypticase soy broth was then transferred onto 5ml brain heart infusion broth (BHIB) and incubated at 37°C for 24 h. Extract filtrate was obtained by first centrifuging 1ml of the incubated BHIB at 4000xg using a Gemmyco centrifuge model PLC-025 to reduce debris and aid filtration. The supernatant was then passed through a 0.20µm filter through a 30mm diameter nylon membrane syringe filter supplied by SMI-LabHut Ltd UK. Sterility check was done on all filtrate by plating an aliquot of the filtrate on MacConkey agar and incubated overnight at 37°C. Plates showing no growth were considered sterile. The BHIB filtrates were screened for verocytotoxicity by a modified method of Rahn et al. (1996).Filtrate was used to cause swelling, rounding or dissemination of vero cells prepared by passageing on monolayer in 96 well micro titre plate. Vero cells for the cell culture assay was prepared by trysinizing with 1X trypsin – EDTA and seeded in 96 well flat bottom micro titre plate at 4 x10^4/well and using1% Glasgow Minimal Essential Medium (GMEM) with addition of Heps buffer as the growth medium. Growth medium was replaced with fresh GMEM after aspiration before cells were infected with filtrate. Undiluted 100µl of the filtrate was transferred to the first well of each plate containing the vero cells and 1:2 dilutions in each of the subsequent wells (i.e. 100µl, 50µl, 25µl, 12.5µl, 6.25µl and 3.125 µl) were then done. The plates were incubated at 370C and examined for cyto-toxic activity after 3hrs, 6hrs, 12h 24h and 48h using an inverted microscope. Degree of verotoxic effect on each of the vero cells were noted and recorded after each examination. Picture of each well was taken before and after infection. Wells containing less than 25% cyto-toxic effect after 48h end point were considered weak, greater than 25% but less than 50% fairly strong, greater than 50% but less than 75% strong, greater than 75% but less than 90% very strong and greater than 90% excellently strong. Tissue culture assay was done at the Moribilic and Related Virus Laboratory, National Veterinary Research Institute (NVRI), Vom, Jos Nigeria.

3. Results

Result of the investigation reveal that of the total 248 samples collected, 107(43.15%) had E. coli isolated from them. Total number of E. coli isolated from the 107 samples was 386. Shiga toxin gene analysis of the isolates reveals that 169(43.78%) had stx1 gene alone, 112 (29.02%) had stx2 gene alone, 3(0.78%) had both stx 1 and stx 2 genes while 103 (26.42%) had none of the two genes. Shiga toxin assay on vero cells indicate that there is a strong relationship between the presence of stx genes and their degree of cyto-toxic effect on vero cells as over 80% isolates without the genes exhibited weak cyto-toxic effect whereas over 80% of those with the genes exhibited more than strong cyto-toxic effect.

This work was done to Isolate and identify stx (Kaplan et al., 1990) reported that although STEC produce other accessory virulence factors, such as intimin (eae) and ‘enterohemolysin A (ehxA), Shiga toxins 1 and 2 are the main virulence factors associated with hemorrhagic colitis and HUS, presumably because they interact with endothelial cells at the site of infection and in the glomeruli and arterioles of the kidney. They also reported that Stx1 and Stx 2 are highly related yet immunologically distinct. Analysis of E. coli isolated in this study, shows those with stx 1 alone (43.75%) to be more while only 0.78% of E. coli isolated from bobozi had both genes. E. coli 0157:H7 which is reported to be the most associated with most STEC outbreak and considered to be very virulent is known to harbour both genes (Gyles, 2007). In spite of the fact that STEC 0157:H7 is reported to be the most virulent; series of STEC outbreaks have identified the non 0157:H7 serotypes like 026:H11, 0103:H2, 0111:NM, 0121:H19, 0145:NM which may not harbour both genes, but only one of the genes to also be very virulent (Mathusa et al., 2010). They opined that various virulence factors are involved in non-O157 STEC pathogenicity; which included the combined presence of both eae and stx genes.

The use of tissue culture assay on Vero cells is one very important method for confirming verotoxin production in microorganism. The profound sensitivity of Vero cells to shiga- toxins (stx) was first observed by Konowalchuk et al., (1977) and cytotoxicity to this cell line has remain a gold standard for confirming putative shiga-toxin producing isolates. This is because Vero cells have a high concentration of globotriaosylceramide (Gb3) and globotetraosylceramide (Gb4) toxin binding receptors in their plasma membranes and will detect all variants of verotoxins. Tissue culture assay on Vero cell to confirm their verotoxigenic capabilities (Plates 1 to 3) in this study show a strong correlation between the presence of stx and their degree of verotoxigenicity (table 3). Over 80% isolates without the genes exhibited weak cytotoxic effect while over 80% of those with the genes exhibited more than strong cytotoxic effect. The result is in agreement with earlier report by Enabulele et al., (2014) on E. coli 0157:H7. The result also is an indication of the fact that presence of stx is a determining factor is the virulence of the Shiga toxin producing E. coli. Rahn, et al.(1996), in their Comparison of Vero cell assay (VCA) and Polymerase chain reaction (PCR) assay as indicators of the presence of verocytotoxigenic Escherichia coli in bovine and human fecal samples, report that although correlation between VCA and PCR results was not absolute, when used in conjunction, these tests complemented one another as predictors of STEC isolation.

4. Discussion

Safe food is very basic to the human population and knowing that the food we eat is safe are key to ensuring good health of the populace. Ready-to-eat foods offers easy access to obtaining energy for man’s daily activity because they are readily available and does not require further processing before they are consumed. They are also relatively cheap and accessible (Mensah et al., 2002; Oranusi and Braide, 2012). Ready to eat foods however have variously been identified as source(s) of transmission of infectious diseases, resulting in various degrees of illness or even death (Egan et al. (2007). This work was done to Isolate and identify E. coli a potential pathogenic microorganism from Bobozi, analyse their vero toxin (stx) gene profile and determine their verotoxigenic potentials on vero cells. The result reveal that an appreciable number of samples (43.15%) collected and analysed had the microorganism. E. coli basically are normal flora of the gastrointestinal tract; however some strains have developed the ability to cause diseases of various pathogenic themes. Amongst these are those referred to as Shiga or Vero toxin producing E. coli.

Disease caused by Shiga toxin-producing Escherichia coli (STEC) is known to range from self-limiting diarrhea to hemorrhagic colitis and haemolytic uremic syndrome (HUS). The O157:H7 serotype is reported to be the most frequently implicated STEC causing hemorrhagic colitis and HUS and it has been isolated from large food borne outbreaks, as well as sporadic cases, in various parts of the world. Although the O157:H7 serotype is not the focus of the work, it is pertinent to mention that the serotype have previously been isolated by this author from some food sources in Nigeria (Enabulele and Urah, 2009; Enabulele et al. 2014). Over 60 STEC serotypes have been implicated in diarrheal disease, and several non-O157:H7 serotypes have also been implicated as the cause of food borne outbreaks and HUS in the United States, Europe, and Australia. Studies from Canada, Europe, Argentina, and Australia suggest that non-O157:H7 STEC infections are as prevalent, or more so, than O157:H7 infections (Fey et al., 2000).
