Abstract

Background: Colorectal cancer (CRC) is the third most common cancer world-wide. The majority of cases occur in the developed world. This prospective study aimed to correlate different human leukocyte antigens (HLA types; HLA DRB1 and DRB3) with the aggressiveness of CRC in Sudanese patients.

Methods: Thirty-three patients with histopathologically confirmed CRC were included in the study. Demographic, clinical and laboratory data were recorded. Molecular typing for HLA DRB1 (DR1, 7 and 17), DRB3 and DRB4 were carried out using PCR-based Sequence-Specific Primers.

Results: Forty percent of the patients were ≤ 50 years; with a male to female ratio of 2:5:1. Rectal bleeding was the commonest presenting symptom. While moderately differentiated adenocarcinoma was the dominant histological type. Duke’s stages B and C were reported in 54.6% and 42.4% of patients, respectively. No patients presented with Duke’s stages A or D. HLA DRB3 was the most frequent allele detected followed by DRB4 and DR17. A higher frequency of the DRB3 allele was found in the peripheral blood when compared with the tumor and apparently normal tissues. HLA DRB3 and DR7 allele frequencies correlated with Duke’s stages B and C but not with age, sex or degree of differentiation, while blood DR17 antigen correlated only with the degree of tumor differentiation.

Conclusion: CRC was found to have a higher occurrence in younger patients. Tumors were aggressive with advance Duke’s stage at presentation. This aggressive nature could possibly be related to either increased HLA DRB3 or DR7 or decreased HLA DR17 levels in the tumor tissue when compared with the blood. No differences between tumor and normal colon tissues were found, in concordance with the multifocality of colon cancer theory.

Keywords: Aggressive Colo-Rectal Cancer; MHC Class II Antigens; Sudan.

1. Introduction

Cancer is the leading cause of death in economically developed countries and the second-leading cause of death in developing countries. (WHO.2008). Despite this, cancer is considered as a lower health priority in Africa compared with other continents. (Siegel R et al.2012). Sudan is no exception as health policies in the country are mainly focused on infectious diseases. According to the National Centre for Health Statistic report, colorectal cancer (CRC) is the third most commonly diagnosed cancer and the third-leading cause of deaths in the USA. (Matanoski G et al.2006). There is limited statistical data on CRC in Sudan. Neither has molecular and immunological characterization of CRC in Sudanese patients been carried out to our knowledge. The first National Cancer Registry in Sudan was established in 2009. It was determined that CRC was the fifth most registered cancer in Khartoum with a rate of 7.1 per 100.000. (Saeed E et al.2014).

The immune system plays an important role in tumor growth and metastasis. (Menon A et al.2004). Evasion and suppression of the immune system are two important abilities that cancer cells acquire during the process of tumorigenesis. (Cavallo F et al.2011). For many decades, CRC has been viewed as an example of a poorly immunogenic tumor; however, recent evidence suggests that there are significant host interactions with this type of cancer. (Shunyakov L et al.2004). This highlighted the presence of immune responses that are associated with improved prognosis, which probably alter the natural history of CRC. (Shunyakov L et al.2004).

The major histocompatibility complex (MHC) antigens have gained interest due to their impact on human diseases. Only recently the role of MHC antigens in cancer has been established, showing that some haplotypes are connected to prognosis and...
MHC class II antigens can be conditionally expressed by all cell types, but are normally expressed only on professional antigen-presenting cells (APCs): macrophages, B cells and especially dendritic cells (DCs). MHC class II molecules are also expressed by a variety of malignant tumors of different embryological origin. (Daar AS et al.1984). The highest frequency of these molecules has been reported in renal cell carcinoma (De Bruin EC et al.2008), medullary breast carcinoma (Lazzaro B et al.2001) and melanomas. (Taramelli D et al.1986).

Conflict information is available about the clinical significance of MHC class II antigen expression in CRC tumor tissues. MHC class II antigen expression in CRC tumors tissues has been reported to be associated with favourable prognosis. (De Bruin EC et al.2008), (Lovig T et al.2006). Others (2006). Others unfavourable unfavorable where it it has shown MHC class II antigen expression in CRC cells was not associated with the clinical course of the disease (Moller P et al.1991, Mulder WM et al.1997, Diederichsen A et al.2003).

Information about MHC class II antigen expression in CRC tumor tissues and its clinical significance may contribute to our understanding of the role of these molecules in the interactions of CRC tumors with the host’s immune system to design new strategies to modulate these interactions. In the present study, the frequencies of HLA class II antigens in a cohort of Sudanese patients with CRC were determined. Possible correlations of these antigens with the clinical data and histopathological characteristics of the tumors were also assessed.

2. Materials and methods

2.1. Ethical consideration

This study was approved by the Ethics and Scientific Committees of the Institute of Endemic Diseases, University of Khartoum. Patients with colorectal cancer diagnosed by colonoscopy and confirmed by histopathology, who were admitted to Ibn Sienna GIT Specialized Centre and Khartoum Teaching Hospital and provided consents were included in the study. Patients younger than 18 years were excluded from the study.

2.2. Study participant information

Demographic, clinical and laboratory data were collected on a uniquely designed case record form (CRF) and the IBM-SPSS Statistics version 20 was used for data entry and analysis. Demographic data included age, sex and other parameters. Clinical information collected included haematological parameters; white blood cell count (4-10 X 109/L), platelet count (130-400 X 109/L), red blood cell count (Male 4.4-5.7 X 1012/L, Female 4.0-5.2 X 1012/L) Renal function information included creatinine concentration (Female 50-90 µmol/L, Male 70-120 µmol/L), sodium level (135-145 mmol/L) and potassium concentration (3.5-5.0 mmol/L).

2.3. Biological specimens

Blood (2.5 mL) was collected into EDTA tubes. Tissue was collected from the tumor site and examined post-operatively by a histopathologist. All tissue biopsies were placed in 25 mL lysis buffer and stored at -20ºC until analysis.

2.4. DNA extraction

DNA extraction from blood was carried out using the guanidine chloride method modified from Blakwell Laboratories Cambridge UK. (Bruce A et al.1996). DNA from tissue was obtained using the GenJet™ Genomic DNA Purification Kit (Thermo Scientific) according to the manufacturer’s protocol.

DNA concentration was measured and purity was determined using a Nanodrop spectrophotometer (Thermo Scientific, Hudson, New Hampshire 03051, USA). Samples with DNA concentrations above 50 ng/ml and purity above 1.8 were used for analysis.

PCR amplicons were run on a 1% agarose gel containing 0.5 µg/µl ethidium bromide. The gel was visualised under UV light using a FireReader Gel documentation system (Uvitec, UK).

2.5. Tissue typing

HLA class II (DRB1, DRB3, DRB4, DRB5) amplification and typing were carried out using HLA-SSP (PCR-based Sequence-Specific Primers) typing kits (Bio-Rad Medical Diagnostics,) according to the manufacturer’s instructions.

The presence or absence of the various amplicons was documented. Characterization of the PCR products was done using Agarose gel electrophoresis (submarine electrophoresis) with the whole volume of the PCR product (10 µL each well) was loaded into the gel wells and electrophoresis at 100 mV for 20 min. The gel was viewed and photographed on the UV illuminator using Canon (PC 1234), 8 Mega Pixel camera.

Gel results interpretation was based on whether a specific band is present on the gel or not. For evaluation, the pattern of the specific bands is transferred to the result sheet.

3. Results

3.1. Demographical data

Thirty-three Sudanese patients with histologically confirmed CRC were included in this study. Seventy per cent were male, with a male: female ratio of 2.5:1. The mean patient age was 55.1±13.5 years, with the youngest patient being 30 years old. The mean age for male patients was 56±13.2 years compared to 52±14.5 years for females. More than a third (39.4 %) of the study participants was below the age of fifty. The remaining participants fell in the age group 51-60 years.

3.2. Clinical data

With regards to tumor location, 54.5% were rectal, 18.2% rectosigmoid, 18.2% left-sided colon and 9.1% right-sided colon. The presence of blood in the rectum was the most common presenting symptom (79%). Weight loss was experienced by 66% of patients. Constipation, abdominal pain, diarrhea and mucus in the rectum were also reported.

Signs of CRC were present in 21% of patients upon physical examination including pallor and abdominal mass. Presence of a rectal mass was found in 50% of patients and was the most commonly encountered sign. Approximately a quarter of the participants were overweight or obese with a mean BMI of 22.3 ± 3.4 kg/m2.

Although blood indices such as total white blood cell count and platelet counts were within the normal range, anaemia was reported in 60.5% of the patients. Renal function and electrolyte levels were found to be within the normal ranges (Mean blood urea level was 24.8 ±7.7 mg/dL, serum creatinine was 0.95 ±0.32mg/dL, Na+ level was 138.9 ± 3.7mmol/L and K+ level was 3.7 ± 0.4mmol/L).

A single patient had a history of benign or malignant disease, namely an ovarian cyst. According to the records 10% of patients
had a family history of benign or malignant tumors and 8% of schistosomiasis.

3.3. Histology data

Adenocarcinoma was the most prevalent histopathological type of cancerous tumor. The degrees of differentiation varied: 24.2% were well differentiated, 15.2% were poorly differentiation and 57.6% were moderately differentiated. Patient's ≤50 years old had a lower prevalence of highly differentiated tumors, although this result was not statistically significant when compared to patients > 50 years old. The opposite was true for poorly differentiated tumors, where patients ≤50 years had an increased prevalence of these tumors compared to patients >50 years with a significantly lower prevalence (p = 0.02). This finding suggests that the tumors in the younger patients were more aggressive in nature (Table 1).

**Statistically significant difference**

With respect to the extent to which the tumors metastasized, Duke’s stages A and D were not observed in the study patients. More than half (54.6%) of the patients were Duke’s stage B with the rest classified as stage C. One patient could not be staged. Duke’s stages B was diagnosed in 58.3% of patients ≤50 years old and in 55% of patients >50 years of age. Duke’s stage C was present in 41.7% and 45% of patients younger and older than 50 years of age, respectively.

3.3. HLA class II

The most frequent MHC class detected in the tumors were HLA DRB3 > HLA DRB4 > DR17 > DR7 (Table 2). The frequencies of the afore-mentioned antigens in blood were 75.8%, 27.3%, 21.2% and 15.2%, respectively (Table 2). Irrespective of age, frequencies of expression of MHC antigens (HLA DRB3, HLA DRB4, DR17 and DR7) in blood, tumors and apparently normal tissues, were similar. Expression of HLA DRB3 allele in peripheral blood was increased to 80% in patients > 50 years old whereas an increase to 69.2% was noted in patients ≤ 50 years old. The DRB3 expression was found to be lower in the tumors of patients in both age groups. The lowest expression of DRB3 was observed in apparently normal tissue; 38.5% in patients ≤ 50 years and 55% in patients >50 years old. Expression of HLA-DR17 in patient's ≤ 50 years old showed the same trend as HLA DRB3, with the highest level of expression being present in the blood (30.8%) and lowest expression being found in normal tissue (7.7%). HLA-DR17 expression followed a different pattern for patients >50 years old, where 15% were observed in tumors and blood and only 5% in apparently normal tissue (Table 3).

No significant differences in HLA DRB3 and DR7 distribution with respect to sex and age were found. A significant difference was however found with the Duke's stages of the tumors for the DRB3 antigen (p = 0.002; Table 4) and for the DR7 antigen (p = 0.04; Table 4). HLA DR17 expression in the peripheral blood differed significantly (p = 0.04) from the degree of tumor differentiation (Table 4).

4. Discussion

Tumor growth has been reported to be affected by the different states of HLA expression. (JanewayCA Jr et al.2001). In various neoplasms, the extent of HLA expression has been associated with the degree of tumor differentiation and disease prognosis. (Janeway CA Jr et al.2001). However, this has been contradicted. This controversy appears to be ascribed to different tissue origins of the various tumors as well as to the heterogeneous expression of individual tumor cells. (Wintzer H et al.1990, Goepel JL et al.1991).

Our study population had twice as many males as females, which was in concordance with previously published data. (Gao R et al.2008 & Abotchie PN et al.2012). It has been implied that estrogen has an influence in the development and progression of colon cancer thereby (Rath-Wolfson L et al.2012), affecting disease outcome. (Koo J H & Rupert WL.2012, Majek O et al.2013).

Our study population presented a higher proportion for the age group detected by Wang et al. (Wang R et al.2014) In the current study, approximately 40% of patients were younger than 50 years old, which presents a higher proportion for the age group detected by Wang et al. (Wang R et al.2015). This finding agreed with previously published reports on CRC in Sudanese patients, (Taha M et al.2015, Mohammed MM et al.2015 & Abdalla A A et al.2007), as well as with reports on Nigerian patients. (Adesanya AA et al.2000).

***statistically significant difference

The results of this study are like those from the Far East which found that the most common histological type of tumor found in CRC are well or moderately differentiated mucinous, adenocarcinomas. (Matsushita K et al. 2006). Furthermore, the anatomical sites of the tumors (rectum or recto-sigmoid) are similar to the current findings. All cases in this study were diagnosed as Duke's stage B or C, with the absence of stage A and D seen. This is in contrast to studies from the East where Duke' stages A and D were reported. (Matsushita K et al.1996). This difference may be due to the advanced nature of CRC in Sudanese patients. This explains the higher percentages of Duke's C and D. (Mohammed MM et al.2015). The absence of patients with Duke's stage A is in line with our hypothesis that states that Sudanese colorectal cancer is aggressive. An increased expression of the HLA DR antigen at the cell surface is seen as a marker for immune stimulation. HLA DRB3 was highly expressed in the DNA samples obtained from blood compared to other sites especially for older patients (> 50 years) while those patients also showed low expression of HLA DR17. HLA DRB3 was also present in high frequencies in blood, tumors as well as apparently normal tissues in older patients (>50 years) compared with younger patients (≤ 50 years). Generally, DR17 frequencies were very low compared to DRB3, with their lowest frequency in apparently normal tissues followed by tumors and blood respectively.

HLA-DR antigens are responsible for tumor-associated antigen recognition by CD4+ T cells. (Zeh HJ et al.2001) HLA-DR antigens are expressed on healthy colorectal epithelium, (Mayer L et al.1991) but are present in colorectal epithelium of inflammatory bowel disease as well as in cancer cells. This is due to the effects of interferon-γ (IFN-γ) Which may or may not be acting in combination with tumor necrosis factor (TNF)-α. (Satoh A et al.2004). Patients with poorly differentiated adenocarcinoma had a higher amount of HLA DR17 in their blood compared to tumor tissue. The normal tissues showed an absence of HLA DR17. With regard to the highly-differentiated adenocarcinoma, no HLA DR17 was detected in the tumor tissue, and no significant difference was found in HLA DR17 frequency in blood and apparently normal tissue.

A higher amount of HLA DR7 antigen was found in patients with Duke's stage C cancer compared to those with Duke's stage B cancer (p = 0.04). The HLA DR7 antigen was not detected in highly differentiated tumors and only an insignificant amount of the antigen was found in the poorly differentiated tumors. The HLA DR7 antigen was not detected in the apparently normal tissues of patients with poorly differentiated adenocarcinomas. In the peripheral blood samples, no difference in antigen concentration was found between different degrees of tumor differentiation.

No significant difference in HLA DRB4, DR7, DR17 and DR1 antigen expression in blood, tumor and apparently normal tissue samples was detected. These findings are contradictory to that of McDougall CJ et al (McDougall CJ et al.1990), where a significant reduction in the expression of HLA class II antigens in colon carcinoma, as compared to control colon mucosa, was found. These authors stated that the expression of HLA class II antigens may vary from colon mucosa obtained from healthy individuals as well as on a histologically healthy colon mucosa obtained from patients with colon cancer. Furthermore, a lack of expression of HLA-DR antigens in healthy colon tissue, with an increased expression in CRC tissues due to IFN-γ has been reported. (Masahiro Iizuka et al.1990). On the contrary, a decreased HLA-DR antigen expression in cancer cells, but increased expression in adjacent non-cancerous tissues has been reported. (Matsushita K et al.2006, Tamiolakis D et al.2005).

HLA DRB3 antigen expression was higher in the peripheral blood of patients >50 years old compared to those ≤50 years old, while HLA DR17 expression was higher in the blood of young patients, ≤50 years compared to tumors and apparently normal mucosa. Neither of these differences, however, were found to be statistically significant. The variable expression levels of the selected HLA class II alleles are widely reflected in literature, and the results can be attributed to the gradual down regulation of these alleles. (Dierssen JW et al.2006). The similarities found between the tumor and apparently normal tissues may be due to the fact that apparently normal tissue is not healthy tissue and may be part of the neoplastic transformation spectrum as was previously described. (Facista A et al.2012).

The extent of HLA-DR and -DP expression on the colorectal cancerous tissues has been found to be inversely proportional to the degree of tumor differentiation. (Masahiro Iizuka et al.1990). This was found to be true for the DR17 antigen which was found in the highest amounts in the peripheral blood of patients with poorly differentiated adenocarcinomas. However, no significant increase in the frequencies of HLA-DRB3 or DR7 in patients with poorly differentiation adenocarcinoma compared to those with well differentiated ones was found. This result may be due to the small sample size of the current study. The higher expression level of DRB3 and DR7 in tumors with Duke's stage C compared to stage B is in line with what was reported by Matsushita et al. (Matsushita K et al.2006). It has been shown that patients with Dukes Stages C and D, and a high HLA-DR antigen expression in cancer cells have a significantly better prognosis compared to those with weak HLA-DR expression. (Masahiro Iizuka et al.1990).

The lack of correlation between HLA-DRB3 and DR7 expression and the degree of differentiation shown in this study has previously been described. (McDougall CJ et al.1990). Also, no correlation with Duke's stages and HLA-DR-expression was described by these authors.
5. Conclusion
This study found that CRC affected a larger number of people under the age of 50 years old than what has previously been stated in literature. CRC tumors tended to become more aggressive in advanced Duke’s stages. This aggressive nature may be attributed to increasing HLA DRB3 and DR7 antigen expression or decreasing HLA DR17 antigen expression in the tumor tissues.

Acknowledgments
The study was supported by the Department of Clinical Pathology and Immunology, Institute of Endemic Diseases, University of Khartoum. We thank all patients and their families for their participation in this study. We also would like to thank Ms. Omima Abdul-Aziz / Researcher, University of Khartoum for her technical support in the lab.
