Abstract

This study aimed to investigate the prophylactic effect of turmeric (Curcuma longa) Rhizome Ethanolic extract (CLRE) at 250 mg/kg as an antioxidant against penconazole induced sub-acute toxicity. Hepatic, renal and testicular pathological changes caused by oxidative damage induced by penconazole in rats were biochemically and histologically evaluated. Male rats were treated with penconazole, via oral route, at doses of 0.5 mg/kg body weight (b.w.; acute reference dose, ARID), 25 mg/kg b.w. (no observed adverse effects level, NOAEL) and 100 mg/kg b.w. (1/20 lethal dose [LD50]) for 28 consecutive days. Penconazole treatments had significant (p < 0.05) and gradual reductions in body and relative testicular weight accompanied by significant elevation in the relative liver and kidney weights. Significant increase serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), lactate dehydrogenase (LDH), gamma-glutamyl transferase (GGT), creatinine (Cre), uric acid and blood glucose was observed due to penconazole treatments. However, total protein and testosterone hormone were significantly decreased. Exposure to penconazole caused increase in lipid peroxidation (LPO) and decreased of liver and kidney antioxidant enzymes activity as catalase (CAT), superoxide dismutase (SOD) and glutathione peroxidase (GPx). Histopathological studies confirmed the ameliorative beneficial effects of turmeric biochemical parameters. On the basis of this study, the use of turmeric rhizomes as a functional food or as a nutraceutical product could be a useful approach to protect individuals who are regularly exposed to penconazole.

Keywords: Antioxidant; Curcuma Longa; Histological Studies; Oxidative Damage Penconazole; Therapeutic Effect.

1. Introduction

Use of fungicides in agriculture and garden caused toxic effects, which vary enormously in their potential. Fungicides can directly applied as canopy foliar and seed treatment or seed treatment. According to their chemical structure, Azoles are grouped into either class of imidazoles or triazoles. Penconazole (1-(2-(2,4-dichlorophenyl)-pentyl)-1H-1,2,4-triazole), is an systemic triazole fungicide and it santifungal activity based on inhibition of lanosterol-14α-demethylase(CYP51) (Yoshida, 1988; Podust et al., 2001), which are phylogenetically widely distributed in mycobacteria, fungi, plants, animals and humans and highly conserved cytochrome P450 monooxygenase (McLean et al. 2002; Lepesheva et al., 2003). Azole compounds are rather lipophilic and penetrate to the cytochrome P450 enzymes within the endoplasmatic reticulum. This lipophilic character partially is responsible for toxicological profile. Inhibition of non-target cytochrome P450 enzymes leads to toxicologically relevant changes in the liver and endocrine system (Zarn et al., 2003). Furthermore, enzymes catalyzing metabolism of xenobiotics develops liver tumors in animal. This has been reported for e.g. cyproconazole, epoxiconazole and tebuconazole and Propiconazole (Zarn et al., 2003; Marquardt Schafer, 2004; Sun et al., 2005).

As a result of intensive application of penconazole in agriculture, residues can remain on treated crops after harvest and can consequently induce toxicological effects on the consumer. Indeed, penconazole exposure induces testicular dysfunction in male albino rats when administered at doses 50 and 100 mg/kg body weight (El-Sharkawy&El-Nisr, 2013). Hepatotoxicity induced by penconazole at a dose of 67 mg/kg b.w. increased malondialdehyde, hydrogen peroxide, and advanced oxidation protein product levels (Chaibane et al., 2015).

Turmeric is a perennial herb derived from the rhizomes of Curcuma longa, which is a member of ginger family (Zingiberaceae). Turmeric rhizomes contain approximately 2% volatile oils mainly consist of alpha and 6-turmerone and monoterpene, 5% curcuminoids, mainly include curcumin, demethoxycurcumin, bis-demethoxycurcumin and dihydrocurcumin as well as turmeric rhizomes contain minerals, carotene and vitamin C (Heath, 2004). Curcumin the principal curcuminoid found in turmeric and generally is used as a spice, pigment and for medicinal purposes. Curcumin may have anti-inflammatory and anticancer activities to prevent and treat the disease. (Kodjio et al., 2016) studied revealed that aqueous extract from Curcuma longa rhizomes has anti-typhoid and antioxidant activities. Based on the previous review, more attention should be paid to the protective effects of natural antioxidants against chemically induced toxicities. Therefore, the goal of the current study was to determine the effect of sub-acute...
penconazole exposure in the liver, kidney and testes male rats and reducing the harmful effect of penconazole by using antioxidant as Curcuma longa Linn ethanolic extract.

2. Materials and methods

2.1. Chemicals

A commercial formulation containing 100 g/L penconazole was used (Topaz, Syngenta, Bale, and Suisse). The oral median lethal dose (LD$_{50}$) of penconazole in rat is 2,000mg according to FAO/WHO (1991). All other chemicals were purchased from Bio-diagnostics Co., Dokki, Giza, Egypt. Other reagents used were of analytical grade.

2.2. Preparation of Curcuma longa linn ethanolic extract

Turmeric (Curcuma longa) rhizomes were purchased from the company of Agricultural Seeds, Herbs and Medicinal Plants, Cairo, Egypt. The dried rhizomes of turmeric were weighed and soaked in 95% ethanol at a ratio of 1:10 plant: ethanol and left for 3 days under shaking and stirring at 25°C. The mixture was filtered and the resulting liquid was concentrated under low pressure and incubated in the dark for a gummy-yellow extract (6.4%, w/w). The concentrated extract was kept in the incubator at 4°C for 3 days to evaporate the ethanol residue. Extracts were dissolved in corn oil before being orally feed to animals in concentrations of 250 mg/kg body weight.

2.3. Determination of total phenolics

Total Phenol content (TPC) of Curcuma longa rhizome ethanolic extract (CLRE) was determined by the Folin Denis colorimetric method using Folin-Ciocalteau reagent (Merck, Darmstadt, Germany) in Gallic acid equivalent (mg GAE/extract)(Zhang et al., 2006). Curcuma longa rhizome ethanolic extract (1 mg) was first dissolved in 1 ml dimethyl sulfoxide (DMSO). Thereafter, 20 µL of the extract was added to 100 µL of Folin-Ciocalteau reagent and incubated in the dark for 3 min. Hundred µL of sodium carbonate solution (1 g/10 mL) was added through the mixture. The final mixture was kept in the dark for 1 h and its absorbance at wavelength 750 nm using Jenway 6305 UV/VIS spectrophotometer (Shimadzu, Japan) was measured. The procedure repeated three times. Linear standard curves were produced by serial dilution of Gallic acid (1 mg/mL DMSO) and the absorbance was measured at wavelength 750 nm using the same aforementioned spectrophotometer. Result, clearly, showed that turmeric had the total phenolic content of 74.81 mg GAE/100 g extract.

2.4. Animals and experimental design

Healthy male Wister rats weighing 125 ± 3 g were obtained from the animal house, Faculty of Medicine, Alexandria University, Egypt. The local committee approved the design of the experiments and the protocol conforms to the guidelines of the National Institutes of Health (NIH). During the whole experimental period, animals were fed with a balanced commercial diet and water ad libitum. Animals maintained in clean plastic cages in the laboratory animal room (23 ± 2°C) and daily dark/light cycle 12/12 hrs. The rats were acclimatized of oral gavages for 28 consecutive days. After acclimatization, the rats were divided into 8 groups, each group of six rats and were maintained as follows:

Group I: Served as a control and were given corn oil (0.5 ml/rat).

Group II: given Curcuma longa rhizomes ethanolic extract (CLRE) in corn oil at a dose of 250 mg/kg body weight daily.

Group III: Given penconazole in corn oil at a dose of 0.5 mg/kg b.w. daily (acute reference dose, ARID, EFSA, 2008).

Group IV: Given penconazole (25 mg/kg.b.w. daily (no observed adverse effects level, NOAEL, Basler et al.,1984; ECHA, 2012).

Group V: Treated with penconazole at a dose of 100 mg/kg b.w. (1/20 LD$_{50}$).

Group VI, VII and VIII: were the same doses of penconazole as in groups III, IV and V, respectively in combination with the Curcuma longa rhizomes extract. During the experimental duration, body weights were recorded and the doses modulated according to weekly body weight gain.

The surviving rats after treatment, in each group, were subjected for 2 days under light diethyl ether anesthetics and the liver, kidney and testes were immediately isolated, cleaned and weighed for biochemical investigation. Liver, kidney and testes were cut into small pieces and kept in 10% formalin solution for histological studies. Specimens from liver, kidney and testis were washed with saline solution, weighed, cut into small pieces, homogenized in 10% (w/v) ice cold 100 mM phosphate buffer (pH 7.4). Homogenates were centrifuged at 10,000g at 4°C for 15 min and the supernatants were used for the measurements of antioxidant enzymes; CAT, SOD and GPx activity. Blood samples were collected from hepatic portal vein in clean sterile vials and left till clotting occurred for 30 min and centrifuged at 3000x g for 15 min for biochemical analysis within one week. Serum samples were aliquot in eppendorf tubes to use each one for one time.

2.5. Biochemical analysis

2.5.1. Enzymes activity

The serum was used to determine the enzyme activities of aspartate aminotransferase (AST; EC 2.6.1.1) by a colorimetric method, alanine:aminotransferase (ALT; EC 2.6.1.2) according to (Reitman & Frankel, 1957), Alkaline phosphatase (ALP; EC 3.1.3.1) as described by Young et al.(1975), γ-glutamyltransferase (γ-GT) as outlined by (Whitfield et al., 1973) and lactate dehydrogenase (LDH; EC 1.1.1.27) activity as indicator of necrotic cell death according to the method of (Vassault et al.,1983).

2.5.2. Biochemical parameters

Concentrations of glucose, total protein, creatinine and uric acid were measured according to the methods of (Tietz, 1995; Gornal et al.,1949; Larsen, 1972; Barham &Trinder, 1972), orderly.

2.5.3. Oxidative stress parameter

Malondialdehyde, in serum, (MDA) as an indicator of lipid peroxidation was determined by a colorimetric method according to (Satoh et al.,1978).

2.5.4. Antioxidant enzymes

Liver and kidney Catalase (CAT; EC 1.11.1.6) were estimated according to the method described by (Aebi 1984) by assaying the hydrolysis of H$_2$O$_2$ and the resulting decrease in absorbance at 510 nm over a 3 min period at 25°C. The activity of CAT enzyme is expressed as U/mg protein.

Superoxide dismutase activity (SOD; EC 1.15.1.1) was assayed by the procedure of (Nishikimi et al., 1972). The assay relies on the ability of the enzyme to inhibit phenazinemethosulphate mediated reaction of nitroblue tetrazollum dye. Glutathione peroxidase (GPx) activity was measured using H$_2$O$_2$ as substrate according to the method described by (Paglia& Valentine, 1987). The reaction was monitored indirectly as the oxidation rate of NADPH at wavelength 240 nm for 3 min. Enzyme activity was expressed as nmol/mg protein.

2.5.5. Testosterone hormones

Serum testosterone level was carried out according to the method reported by (Tietz, 1995) using International Immune Diagnostics Kits.
2.6. Histological studies

Liver, kidney and testis samples, from all rats, were excised and fixed in 10% neutral formalin buffer for histological examination. The samples were processed using graded ethanol series and embedded in paraffin. Tissue sections (5-μm thick) were cut and stained with hematoxylin and eosin (H&E). All sections were evaluated for the degree of liver, kidney and testis injury and assigned for severity of changes using scores on a scale of none (-), mild (+), moderate (+++) and severe (++++) damages (Bancroft et al. 1996).

2.7. Statistical analysis

Appropriate analysis of variance on obtained results was achieved using one-way analysis of variance (Software SPSS version 9.2). Comparisons among different mean treatments were performed using Duncan’s Multiple Range Test (SAS, 2013).

3. Results

During the study period, there were no clinical signs of toxicity in any group treatment.

3.1. Body and organ weights

Results of Table (1); indicated that, there were no significant differences in body and relative liver, kidney and testicular weights between Curcuma longa rhizomes extract and untreated rats due to the exposure during sub-acute toxicity. However, the treated groups with penconazole dosages (0.5, 25, and 100 mg/kg b.w) exhibited significant (p < 0.05) and gradual weight loss in the body and relative testicular weights accompanied by significant increments in the relative liver and kidney weights. Unfortunately, when CLRE extract were administrated to penconazole treated groups, significant enhancements of all above-mentioned parameters were detected.

### Table 1: Effect of Penconazole (Pen.) Treatments on Body and Relative Liver, Kidney and Testes Weights of Rats and the Ameliorative Role of C. Longa Rhizome Ethanical Extract (CLRE).

Each value is a mean of 6 rats ± S.E.M; a, b, c, d values are not sharing superscripts letters (a, b, c, d) differ significantly at p < 0.05; % of body weight change/week = [(final b. w t. – initial b. wt.)/initial b. wt.]/no of weeks X 100.

3.2. Biochemical measurements

The oral administration of Curcuma longa rhizomes extract (CLRE) to normal rats did not reflect any changes in all biochemical tested parameters compared to the normal control (Tables 2, 3 & 4).

Data tabulated in Table (2) clarified that, after 28 days of penconazole administration at 0.5, 25, and 100 mg/kg b.w. ALT, AST, ALP, γ-GT and LDH activities were significantly increased as compared with control. The increase in activity for each detrimental enzyme was more pronounced at the higher dose of penconazole (100mg/kg b.w.) than those of intermediate dose (25 mg/kg b. w.) and the lower one (0.5 mg/kg b. w.).

In contrast, the treated groups with penconazole at 0.5, 25, and 100 mg/kg b.w. significantly (P<0.05), decreased total protein in comparison with the untreated rats. On the other hand, increasing penconazole from 0.5 to 25 and furtherly to100 mg/kg b.w., progressively and significantly, elevated serum glucose level in treated groups compared with the control. However, co-administration of CLRE extract to the treated rats with penconazole induced a partial recovery in the above-mentioned parameters.

Fig. 1, represents the changes in both levels of serum creatinine and uric acid in various experimental groups. Penconazole treatment (irrespective of the concentration used), gradually and significantly, elevated serum creatinine and uric acid levels as compared to control group. The highest penconazole dose (100 mg/kg b.w.), the highest levels were the serum creatinine and uric acid. However, oral administration of CLRE extract to normal rats produced no changes in the cited above biochemical parameters when compared to the untreated control. Treatment with CLRE extract markedly restored activities to the normal levels.

Fig. 2, illustrated that, the penconazole treatments, statistically, lowered the testosterone hormone concentrations in serum (p<0.05) than the control. The lowest significant testosterone concentration was recorded with the high penconazole dose 100 mg/kg b.w. (2.89 ng/ml). It was noticed that, administration of CLRE to penconazole treated groups caused pronounced increase in testosterone concentration compared to the control rats (4.81 ng/ml).

3.3. Oxidative stress markers

Treated groups with penconazole at 0.5, 25 and 100 mg/kg b.w. led to significant increments (p < 0.05) over the control in lipid peroxidation of serum MDA levels by 33, 36, and 44%, respectively. However, the combined treatments of penconazole at 0.5, 25 and 100 mg/kg b.w. and CLRE extract reduced the augmentation of serum MDA levels to 7, 10 and 19%, orderly (Fig. 3). The activities of CAT, SOD and GPx in liver and kidney under the effect of penconazole at different concentrations and their combination with CLRE extract are illustrated in Table (3). Penconazole treated rate groups accompanied with injury and extensive oxidative damage due to the significant reduction in the activities of CAT, SOD and GPx in liver and kidney as compared to the untreated group. However, the addition of CLRE extract to treated-penconazole groups, significantly, increased antioxidant parameters; CAT, SOD and GPx activities in liver and kidney. On the other hand, treatment with CLRE extract alone did not reflect any significant alteration in SOD, GPx and CAT activity compared to control treatment.
of C. longa rhizome ethanolic extract (CLRE) on the serum biochemical factors in penconazole (Pen.) induced male rats.

3.4. Histopathological examination

The representative pictures of histopathological examination in the liver, kidney and testis tissues are shown in Fig.4, 5 & 6. The semi-quantitative histological scoring of liver, kidney and testis damage was presented in Table 4. Liver sections from the control group rats showed normal hepatic cytoarchitecture (Fig. 4A). They formed of hepatocytes radiating from central vein to the periphery of the lobules. Liver lobules of penconazole dosages at 0.5, 25 and 100 mg/kg b.w. showed focal hepatic necrosis, congestion of central vein and focal hepatic necrosis associated with inflammatory cells infiltration and portal infiltration with inflammatory cells and hydropic degeneration of hepatocytes, consequently (Figs. 4, C, E&G). On the other side, Histopathological examination of liver of CLRE extract to penconazole treated groups exhibited that hepatocytes was completely recovered at the low penconazole dose (0.5 mg/kg b.w). However, partial recovery was noticed at 25, and 100 mg/kg b.w. Where, the severity of the above cited histological abnormalities ranged from moderate to severe degree. Kidney sections from the control group rats and CLRE extract-treated rats showed the normal histological structure of renal parenchyma (Fig. 5A). However, abnormalities in kidney of penconazole dosages (0.5, 25, and 100 mg/kg b.w) treated rats were detected in cystic dilatation of renal tubules with intraluminal eosinophilic protein cast, vacuolation of epithelial lining renal tubules and focal necrosis of renal tubules associated with inflammatory cells infiltration, respectively (Figs. 6, C, E&G). It was observed that the co-administration of the turmeric extract
with penconazole showed different degrees of improvement in their histological structure in comparison to the treated groups.

Testicular sections from the control group rats, CLRE extract and penconazole groups -treated rats showed the necrotic changes of seminiferous tubules were recorded; its degree of damage ranged from apparently normal-looking seminiferous tubules to degenerated seminiferous epithelium lined by single layer of cells, consisting of sertoli cells and few spermatogonia (Figs. 6C, E&G). Penconazole dosages (0.5, 25mg/kg b.w) treated rats showed marked degeneration and necrosis of spermatogoncal cells lining seminiferous tubules with formation of spermatid giant cells, and congestion of testicular blood vessel. However, dose of 100mg/kg b.w showed marked degeneration and necrosis of spermatogoncal cells lining seminiferous tubules and congestion of testicular blood vessel. On the other hand, the co-administration of the turmericic extract with penconazole showed marked improvement in their histological structure in comparison to the treated groups (3, 4 and 5) alone. Where, histological structure was more or less similar to control group.

Fig. 6: Histopathological examination of rat testes. (A, B) showing normal Seminiferous tubules with normal spermatogoncal cells and complete spermatogenesis with sperm production in control and CLRE. 0.5 Mg/Kg penconazole-treated animal testes (C) showing marked degeneration and necrosis of spermatogoncal cells lining seminiferous tubules with formation of spermatid giant sells and plus CLRE (D) showing no histopathological changes, 25 Mg/Kg penconazole -treated rat (E), showing marked degeneration and necrosis of spermatogoncal cells lining seminiferous tubules and congestion of testicular blood vessel and plus CLRE (F) showing no histopathological changes, 100 Mg/Kg penconazole-treated rat (G) showing focal necrosis of testicular tubules associated with inflammatory cells infiltration and plus CLRE (H) showing slight hypertrophy of glomerular tuft and few interstitial inflammatory cells infiltration.
lution of triglycerides and release enzymes into the bloodstream caused emergence of necrosis in cells of liver tissue. The liver is a major organ of protein synthesis. Therefore, any disease in liver can cause damage of hepatocytes with changes in protein and free amino acid metabolism leading to decrease synthesis and increase wasting via catabolism (Yousef et al. 2006, Wallace 2007, El-Shafey et al. 2011, Eid et al. 2013). The decreased level of total proteins in serum due to treated-penconazole rats reflect the severity of liver toxicity as reported by (Chaabane et al. 2015).

The treated-penconazole rats showed augmentation in serum glucose level which associated with a positive significant influence in daily water intake. This suggested that a longer exposure period of penconazole could probably induce diabetes. The obtained results are in line with the results of (Abdollahi et al. 2004) who reported that, treated-malathion rat’s stimulated glycosgenolysis in several organs and of glucogenogenesis in liver, leading to the release of glucose into the blood.

The collective result supports the suggestion; treatment with turmeric extract could provide appropriate host to protect the hepatocytes from progressive damage. The increase of uric acid concentration is a demonstration of impaired kidney function since the organ primarily excretes urea in the urine. Elevated creatinine is correlated with an increased protein catabolism, as creatinine is the end product of protein catabolism. Obviously, our results revealed significant increases in serum uric acid and creatinine concentrations following the sub-acute penconazole administration compared to the control. Increasing serum uric acid and creatinine concentrations may be due to the reduction in glomerular filtration in the kidney and dysfunction of the kidney tubules (Walmsley & White 1994). Similar findings were demonstrated by (Eisak & Zidan 2010). The increase in creatinine due to penconazole administration was, also, correlated closely with the histopathological changes in the kidney as shown in figure (5).

Table 4: Semi-quantitative scoring of architectural damage on histopathological examination of the liver, kidney and testes rat in different treatment groups.

4. Discussion

Penconazole is an agricultural fungicide, which is used by foliar application to control a wide range of diseases in fruits and vegetables. As a result of their wide use, fungicide residues were found to contaminate crops and water resources (Pan & Ho 2004 & Wang et al. 2005). The scope of this study is to investigate the sub acute exposure of the penconazole fungicide on histopathology and function of liver, kidney and testes in albino rats and to examine the prophylactic effect of ethanolic extract of Curcuma longa against penconazole induced toxicity. In toxicological studies, weights of body and relative organ are important criteria for evaluation of organ toxicity. The results showed that, the continuous exposure to penconazole at the doses of 0.5, 25 and 100 mg/kg b.w., orall feeding, for 28 days continuously, caused significant reductions in body weight and relative weights of the testes than control. However, significant increment in the relative liver and kidney weights were detected compared to the control. The reduction in body weight may be attributed to the combined action of cholinergic and oxidative stress(Grance et al. 2008, Dirican & Kalender 2011, Saafi et al. 2011) and/or due to the overall increased degradation of lipids and proteins. Moreover, the noticeable increments in liver and kidney weights could be due to the relationship between both liver and kidney weights increase and various toxicological effects or the reduction in body weight gain of experimental animals. These results agreed with the findings of (El-Sharkawy & El-Nisr 2013, Chaabane et al.2015). However, co-administration of CLRE extract treatments ameliorated body and liver weights of intoxicated rats.

Liver is the largest organ in the vertebrate body and is the major site of xenobiotic metabolism and excretion that plays a key role in the detoxification process. Therefore, any injury or impairment type of its function produces hepatotoxicity and causes health complications. Liver enzymes such as AST, ALT, ALP, γ-GT and LDH are the most commonly used biomarkers of liver injury. In the present work, the activities of these enzymes exhibited marked elevation indicating hepatocellular damage. The elevation in the activities of these enzymes could be due to some conditions including muscle damage, intestinal and hepatic injury and toxic hepatitis (Farkas et al. 2004). Confirming with this interpretation (Alhazzou 2007) displayed that, destruction of cells and damage of tissue caused elevated enzymes in liver as well as accumu-
tive principle of turmeric extract ameliorated diabetic nephropathy in rats and the anti-oxidative mechanism being responsible for the nephro-protective action of curcumin, which might be potentially useful in some kidney diseases by preventing renal inflammation as reported by (Sharma et al. 2006). Turmeric extract was found to possess multiple therapeutic activities that block the cardiac, hepatic and renal toxicities induced by arsenic trioxide (Saxena et al. 2009) and had as a free radical scavenger activity. In this respect (Krup et al.2013) reported that, the ethanol extract of Curcuma longa rhizomes showed a significant hepato-protective effect when orally administrated at 250 and 500 mg/kg b.w. Exposure of experimental animals to pesticides is known to induce lipid peroxidation in various tissues, which leads to adverse biological effects (El-Demerdash et al. 2004). The inhibition activity on CAT, SOD and GPx and enhance of lipid peroxidation in treated-penconazole rats could be explained based on induction free radicals. Highly reactive oxygen metabolites, especially hydroxyl radicals, act on unsaturated fatty acids of phospholipid components of membranes to produce malondialdehyde, a LPO product. Under normal circumstances, the imbalance between production of oxygen free radicals (OFRs) and antioxidant defenses in the body is called oxidative stress, which has important health implications (Wei et al. 2006). Phenolic compounds are powerful antioxidants, which defend the human body against free radicals. Usually, the deleterious effects of oxidative stress, result from the generation of free radicals, are counteracted by endogenous antioxidant enzymes such as CAT, SOD, and GPx. Hence, results from the current study suggest that, turmeric ethnol extract could reduce liver, kidney and testes injury induced by penconazole. The mechanism by which this extract exerted its protective action could be due to wide range of bioactive compounds i.e. antioxidant activity including phenolics. The principle isolated of Curcuma longa Linn rhizome is active flavonoid curcuminoids, which is a mixture of curcumin (diferuloylmethane), monodemethoxycurcumin and bisdemethoxycurcumin. Curcumin represents up approximately 90% of the curcuminoids content in turmeric (Heath 2004, Sandur et al. 2007). Turmeric aqueous extract have O2 scavenging activity protected the cells from induced cell death. Also, it causes a marked decrease in malondialdehyde (MDA) and, significantly, elevated the antioxidant enzymes activity; glutathione peroxidase, and catalase (Koo et al. 2004). Turmeric is considered being abundant in phenolic components such as curcuminoids that grab the antioxidant activity of turmeric curcuminoids avert the development of free radicals (Maizira et al. 2011). Results indicated that, concentration of hormone testosterone in serum of the exposed penconazole rats, significantly, were lower than the control. The decrease in testosterone hormone concentration may be contributed to testicular hypo function. In addition; the obtained data showed a dose-dependent difference obtained in the most recorded parameters. The differences at p<0.05 where statistically significant dose 100mg/kg b.w. was among toxic effects of penconazole on testes of exposed groups may be attributed to penconazole fungicides that mimic steroid hormones, and are called endocrine disruptive chemicals, because they alter the expression of endocrine-regulated gene (Perreault, 1997; Makame et al. 2004). Penconazole inhibits testosterone production (FAO/WHO, 1998). Penconazole was inhibited aromatase activity, decrease estrogens production and increase androgens availability (Trosken et al. 2004). These results are in agreement with (El-Sharkawy & El-Nisr 2013). A testes was the organ of choice as it is used as a sensitive indicator to male reproductivity. A role of penconazole in endocrine disrupting mediated effects and strongly suggesting a possible mode of action in thyroid carcinogenesis (Perdichizzi et al. 2014).

5. Conclusion
In summary, we conclude that penconazole exposure leads to hepato-nephrotoxicity and fertility toxicity in adult rats as revealed by an increase of lipid peroxidation and an alteration of antioxidant status, associated with liver and kidney histological disorders. Penconazole inhibited testosterone production. Restriction in the use of penconazole as a fungicide to protect crops should be taken in consideration. Prevention of penconazole exposure to farm animals and regular monitoring of residues in the environment must be applied. The present results demonstrated that the turmeric extract protects the liver and kidney tissues against toxic effects of penconazole. On the basis of this study, the use of turmeric rhamnoids as a functional food or as a nutraceutical product could be a useful approach to protect individuals who are regularly exposed to penconazole.

Our findings supported that the use of tumeric extract may therefore be more effective for clinical purposes with antioxidant properties. However, further investigations will be done to elucidate the mechanism of protection and potential usefulness of these plant extract as a source of protective agents against drugs or xenobiotics toxicity in clinical trials.
