Abstract

The rapid growth in digitization transmission of information in the form of RGB image. During the process transmission of the image in a channel, some data may be degraded due to noise. At receiver side error in data has to be detected and corrected. Hamming code is one of the popular techniques for error detection and correction. In this paper new algorithm proposed for encryption and decryption of RGB image with DNA cryptography and hamming code for secure transmission, and correction. this algorithm first encodes data to hamming code and encrypted to DNA code. Two-bit error detection and correction for each pixel of the image can be performed.DNA code improves security and use of the Hamming code for error detection and correction. For the image of size 256*256 pixel image, it corrects up to 2*256*256 bits in RGB image. The RGB image encryption and decryption design using Verilog and implemented using FPGA (Field Programmable Gate Array).

Keywords: RGB Image, Hamming code, DNA cryptography, Error detection and correction.

1. Introduction

In The recent years, rapid growth in technology in the form of digitization and media. The transmission of information not only in the form of data but also in the form of an image. Mainly images are used in many application such as social media, satellite communication, military, medical imaging and advertising etc. These images are to be transmitted through unsecured channel or platform such as hard drive, emails, server etc, the main issue of protecting privacy, confidentiality, genuineness, and accuracy is a major concern. Information in the form of image exchanged in the presence of third parties. There is a need for algorithms to hide the information for security. There are no of algorithms designed for data security used in cryptography domain. Cryptography technique used to hide the information in the ciphertext or by using the key. cryptography use symmetric and asymmetric algorithms. With the recent growth in DNA cryptography methods applied from text to image.

The digital image is two-dimensional data, each pixel represents different color intensity varies from 0 to 255 values in decimal represented in 8-bit form. Due to the large amount of data conventional encryption methods such as AES and DES etc not used. DNA encryption explained [1-2] using conventional methods. Different encryption methods based on DNA cryptography explained in [3-4]. DNA encryption algorithm using a one-time pad (OTP), the chaotic map used to encrypt images [5],[6] Lorenz system along with DNA cryptography to encrypt color image. RGB image encryption using DNA encoding and elliptic curve Diffie-Hellman cryptography [7].

A. DNA Encoding

DNA means deoxyribonucleic acid formed using 4 basic nucleic acids namely Adenine(A), Cytosine(C), Guanine(G), Thymine(T), the pairs (A,T) and (C,G) are complement each other Binary

values assigned to A,C,G, and T are shown in TABLE:1, Fig1: show structure of DNA.

Fig. 1: Structure of DNA

B. Hamming Code

The major issue in communication is the secure transmission of data from a transmitter to the receiver, there are no of technologies used for error correction one is the Hamming code used for error detection and correction. Hamming code is linear block codes improved over parity code method for error detection and correction by using Forward Error Correction (FEC). In digital communication mainly military, security and data compression immune to noise, among various methods FEC is efficient [8,9,10]. Redundant bits are added including parity bit at the transmitter and removed at receiver. Usage of parity enables

 \odot

detecting and correcting single bit error in received messages. For hamming code depend on redundant bits data transmitted, for example, 4 bits of data 3 redundant bits of data are added general formula for representation of hamming code is

(2ⁿ-1, 2ⁿ-n-1),

- Where n = no of redundant bits;
 - 2ⁿ-1=block size;
 - 2ⁿ-n-1=no of data bits;

For 4-bit data hamming code represented as (7,4) and extra parity bit added during transmission, by using parity bits hamming code can detect and correct single bit error. (7,4) Hamming code algorithm [11,12,13] implemented using VLSI including error

correction explained.

2. Encryption Process

The RGB image is a combination of three channels as RED, GREEN and BLUE channels, Each channel image combination of pixel values of different levels vary from 0 to 255 in decimal value. DNA cryptography with different algorithms used in digital coding [14,15]. Here in this the process of converting the RGB image into DNA code including hamming code to each pixel of an image. The process of encryption is shown in Fig: 2.

Fig. 2: Encryption process flow A) Flowchart, B) Diagrammatic representation.

As shown in Fig2B: RGB image is taken as input and split the image into Red, Green, Blue channels respectively channel and convert channels to the binary equivalent of pixels and group every 4 bits of binary. Add hamming code including parity to 4bit binary and then encrypt binary data to DNA code, the RGB image is encrypted to DNA code and transmitted as three separate channels i.e Red, Green, Blue channels of DNA encrypted data. Steps of Encryption process flow :

STEP1: 8-bit RGB image is considered as the input image.

STEP2: Split RGB image into separate Red, Green, Blue channels.

STEP3: Convert each pixel value in decimal into 8-bit binary.

STEP4: Add hamming code to each 4bits of the pixel along with parity bit.

STEP 5: Binary hamming code is converted into DNA code in the form of ACGT, Assign binary values A=00, C=01, G=10, T=11 respectively.

Consider 4 bits of binary data and convert data to hamming code example shown below.

Input data: D4D3D2D1

Code data bits (C1, C2, C3):

 $C1 = D4 \oplus D2 \oplus D1;$ $C2 = D4 \oplus D3 \oplus D1;$ $C3 = D4 \oplus D3 \oplus D2;$

Parity bit
$$P=C1 \oplus C2 \oplus C3 \oplus D4 \oplus D3 \oplus D2 \oplus D1$$

Hamming code = $P D_4 D_3 D_2 C3 D_1 C2 C1$;

For four-bit data hamming code have length 8bit and code bits are added for 1,2 and 4thbit positions, parity bit added at MSB position.

Example: Input data =1101;

Code bits are	C1=1	0	1=0;
	C2=1	1	·1 =1;
	C3=1	1	0=0;

P=1 1 0 0 1 1 0=0; Hamming code =01100110;

A fear a ddia a harming a sada

After adding hamming code to each 4bit of pixel each pixel 8bit is converted to 16 bit data .

Fig:3 shows pixel value converted to hamming code and then to DNA encrypted code.

Fig. 3: Pixel value to DNA code conversion

3. Decryption Process

At receiver end during decryption process encrypted DNA code of Red, Green, Blue channels is taken as input. Complete flow for decryption process shown in fig:4.

DNA code is converted to binary hamming code, then to equivalent decimal and combines to get RGB image [16].

As shown in fig:4B) Received DNA code is decrypted to hamming code and then converted to four bit binary equivalent and group binary values to get image for channels and combine channels to get RGB image.

Fig. 4: Decryption process of RGB image. A) Flowchart, B) Diagrammatic representation of flow

Steps of decryption process:

STEP1: Encrypted DNA code of R, G, and B channels are taken as input.

STPE2: Convert DNA code to equivalent binary data of hamming code.

STEP3: Hamming code for the 8-bit binary pixel value conversion. During conversion process error detection by using check bits in hamming code and data can be corrected.

STEP4: Pixel value in binary to Decimal equivalent of Red, green, Blue channels.

STEP5: Combine three (RED, GREEN, BLUE) channels to get RGB image.

4. Simulation Results

RGB image encrypted to DNA code conversion process explained in fig: 2 conversion of each pixel value of the image to equivalent binary and add hamming code including parity bit to every 4 bits of the pixel, binary data converted to DNA code in the form of A, C, G and T values. Simulation results for encryption how RGB image split into three channels shown in Fig:5 and binary pixel values of Red, Green and Blue channels converted to DNA encryption output shown in fig:6. Encrypted data is transmitted to the transmitter as three separate channels.

BLUE Channel

Fig. 6: DNA encryption of RGB image.

At receiver during decryption process conversion of DNA to image flow explained in Fig: 4. At the receiver end, it can detect an error occurred in pixels value by using check bits at receiver. The conversion of DNA code to binary pixel values shown in Fig:7. An error has occurred can be checked during transmission by using check bits for hamming code, If check bit value is zero then received data has no error. If check bit is not zero depending on check bit value receiver can predict the position of error and it can be corrected. Decryption of image, DNA code converted to pixel value shown in fig:7. Recovered pixel values are converted to red, green and blue channels and combine channels to get RGB image is shown in fig:8.

TABLE 1.

5. Error Detection and Correction

A. Error Detection

Hamming code used for the variable length of data, In this paper, perform hamming code for 4bits of the pixel. During encryption process code bits are added for hamming code discussed during the encryption process. By using check bits receiver can check data received correctly or not, If data received correctly the value of check bits are 000 else data received have some error, Depend on the value of check bits position of error can be known.

Check data (3 bit)A:

 $A1 = C1 \oplus D4 \oplus D2 \oplus D1;$

 $A2 = C2 \oplus D4 \oplus D3 \oplus D1;$

$A3 = C3 \oplus D4 \oplus D3 \oplus D2;$

Received end check bit data generated using received hamming 8bit code including parity. If A=000 no error, if it is having some value then there exists an error by changing value 0 to 1 or 1 to 0.

Table 1: Error Detection Using Check bits

error detection for using hamming code check bits shown in

Check data	Error bit position	Correct	ted data
A3A2A1			
000	0	No cl	nange
001	1	0 to 1	1 to 0
010	2	0 to 1	1 to 0

B. Error Correction

Error correction for hamming code received data by using check bits and parity bits. Error position in MSB bit i.e 8th bit can be known by using parity for data. Hamming code for 4-bit data given as input and error position detected using check bit and parity. Single bit error correction can be implemented using both check and parity bits, sometimes an error occurs in parity bit position also it cannot be detected by check bits but it can be detected by using parity, Table :2 describe error correction for one bit and more than one bit by using parity and check bit .If more than a one-bit error occurs it can not be corrected. Error correction for one bit shown in Fig10.

7. Conclusions

A secured system designed for Encryption and decryption system for RGB image using DNA cryptography, Hamming code added to every 4 bits of the pixel of the image. It improves error correction up to 2bits for each pixel value, considers 256*256 pixel image get error correction up to 2*256*256 bits. Secured image transmission using DNA cryptography achieved and error detection and correction by using hamming code. It is designed in Verilog and implemented using FPGA maximum delay for implementation of the circuit is 6.37ns.
