Abstract

The Water is the most valuable because it is a basic need of all humans, in these days water supply department are facing problem because of less amount of water due to less rainfall, lowering of ground water in spite of all these problems water leakage from pipelines while supplying and also no monitoring of water distribution and controlling. With increment in population, neighborhoods have expanded as a result of this reason water has turned into a major issue which influences in distribution, conservation, consumption and also the quality so, to overcome all these problems and create system economical there’s want of correct observance and dominant system. In this paper, we are proposing a system which can detect the leakages, monitoring and controlling if water supply in pipelines. Sensors places in the tank which continuously informs the water level of water in the tank. The motor functioning will be automatically turn on and when tank is about to fill up it will cut off.

Keywords: Arduino Uno, Flow Sensor, ESP8266, LCD, GSM.

1. Introduction

In India more than 30% of people live in urban areas that are expected to double in population by 2050. With a increasing economy and dynamical lifestyles the pressure on water resources used for supply purpose is increasing. Most cities in India are with lack of water, with no city having 24/7 water supply. Water is very important for human and animal life for maintain ecological balance and for economic development and controlling of all kinds. Water is a fundamental need of every people everyone must save the water for the future. Water management in the cities has become a big issue due to lack of rainfall, increase in population many people are facing water problem because they don’t have enough amount of water for daily needs. Management of water resource in India is importance to sustain one billion plus population. Because of improper monitoring water cannot be supplied properly, in cities some areas can get proper supply of water and the others areas may have irregular supply there is a need of continuous observing and controlling, of water supply booking and appropriate circulation. Different issues are extreme utilization, flood of tanks and spillage in pipes, interruption in the water supply in the city. For the leakage of the water pipelines there are many other process and also we have some the protocols for water leakage detection and some other for monitoring and controlling. In this paper we discuss about water leakage detection, monitoring and controlling using advanced techniques.

In some papers we have Smart Water Leakage Detection and Monitoring Device By BhekiSithole, SuvendiRimer, Khmaies, C.Mikeka, J.Pinifolo; In this paper they have explained about water leakage detection and monitoring. This paper is exhibiting a variable minimal effort device which is equipped for deciding conceivable spillages in the client’s property and announcing current household water consumption levels in real time. Flow meter sensors are used to measure the quantity of water consumed by consumer. In turn, the flow rates of water and amount of water used will be displayed in LCD and the complete information will be sent to website. This system has been efficiently and precisely intended to limit commercial losses.

An Enchanced Underground Water Pipeline Water Leakage Monitoring And Detection System Using Wireless Sensor Network ByM.Jayalakshmi, Dr.V.Gomathi: This paper depicts about the plan and execution of a water spillage observing and discovery framework to screen and distinguish spill with the assistance of remote arranged sensors. The goal of this upgraded framework is to identify conceivable underground water spillage for private water pipes that are checked from a PC. In this way, a powerful and dependable wireless sensor organize which forms little Printed Circuit Boards (PCB), information from remote sensors of various sorts (acoustic, weight, temperature, stream rate and so on) are gathered and observed on a PC to distinguish the correct spillage position. Once a break is identified the water utility must make restorative move to limit water misfortunes in the dispersion framework. Along these lines the proposed framework will be utilized to spare water and decreases the supplancing cost.

2. Proposed System

Before knowing about the proposed system let us know how water supply is done through pipelines. Water from rivers and lakes reach to the particular area tanks for easy supply to different houses for drinking, cooking and cleaning. We have numerous pipelines and can be any one is closed, the water supply system will be affected. The water leakages are usually due to some causes such as, pipe cracking, pollution, washing, etc. However, the water leakages can be due to some other causes like sandstorms, rocks, etc. We provide the system to find out the water leakages and for the pipeline leakages. The proposed system is used for the leakage areas with the help of water leakage detection and monitoring device. The system consists of Arduino Uno, Flow Sensor, ESP8266, LCD, GSM.
es in an area. The water which are reached to tanks should be sup-
plied to houses equally or else there may be in sufficient of water
so for that purpose monitoring of water supply through pipelines
should be done and in same way the controlling of water in pipe-
lines should be done due to lack of water. To manage all these
problems we need to check the condition of water pipelines before
supplying and if any leakage is present in middle of the pipeline
that may cause many problems to the people stay in houses. And if
any leakage occurs in pipelines it causes wastage of water. The
main objective of our project is to design a system which can de-
tect the leakage of pipeline while the supply of water and if any
leakage is present in the pipe then automatically the motor will off
and the supply stops for that pipe not to have more wastage of
water and to manage the flow of water which are supplied so that
all can get equal amount of water by using this system.

3. Related Work

System consist of Arduino board, LCD, ESP8266, GSM module,
flow sensor, power supply each block is explained below. We are
working on a prototype model The following block diagram
shows the hardware used in the system.

![Block diagram of water system](image_url)

3.1. Arduino Uno

Arduino uno could be a microcontroller board in less weight of the
ATmega328P. It has fourteen advanced input/output pins (which 6
can be used as Pulse Width Modulation outputs), 6 analog inputs,
a 16MHz quartz crystal, a USB connection, a power jack, and a
reset button. Arduino board contains all the supported pins needed
for the microcontroller; connect it to a computer with a USB cable
or connect to power supply with a AC-to-DC adapter or battery to
on the board. In this project we use arduino board for connecting
all the required components and power supply is also being done
using this board. The inputs and outputs should be connected
properly. While connecting the board to remaining devices proper
care should be taken.

3.2. Flow Sensors

The water flow sensor model used in project is YF-S201, its work-
ing range: 1-30L/Min and water pressure: <= 1.75MpS. The ar-
duino flow sensor works on principle of hall effect. Flow sensor is
used to determine the mass flow rate of inflow and outflow of
water used in the pipelines. In this we use water flow sensor it con-
ists of a plastic valve body, a water rotor and a hall effect
sensor. This flow sensor is arranged to both sides of the pipe
which can measure the inflow and outflow when water flows
through sensor the rotor moves. Speed of water changes with the
flow of water. By using this flow sensor can measure the flow rate
of water flows in pipelines. Flow sensor is interfaced with arduino
board with 3 wires of flow sensor they are 5V power sup-
ply(Vcc), Ground(Gnd), and signal/pulse line. Connect Vcc and
GND of flow sensor to Vcc and Gnd of arduino board, the pulse
line of the flow sensor is connected to digital pin 2 of arduino.

3.3. Liquid Crystal Display (LCD)

A Liquid Crystal Display (LCD) is a level board show that uses
the high balancing properties of fluid crystal. Fluid crystals don’t
transmit light straightforwardly. In this project LCD display is
utilized for the show of inflow and outflow of water through pipe-
lines. If there is any change in the flow of water the leakage will
be detected the in the LCD it show that the leakage of water is
detected. LCD is interfaced with arduino board by connecting the
LCD pins to arduino.

3.4. ESP8266

We use ESP8266 Wi-Fi module which is of low cost. It fully con-
stituts of TCP/IP stack and microcontroller unit (MCU). It can con-
trol any electrical device by using internet from any place in the
world. It is easy to use with arduino. For any IoT application this
wifi chip can be used for easy connection. ESP8266 module has 3
operational modes they are Access Purpose (AP), Station (STA).
Both access purpose and station. Upload ESP8266 code to arduino
board from Tools > board > generic ESP8266 module there are
three main steps arduino setup, installing ESP8266 platform, con-
trolling input and output.

3.6. GSM

Global System for Mobile communication (GSM) is a computer-
ized portable communication framework that is broadly utilized as
a part of numerous of world. GSM utilizes a variety of the Time
Division Multiple Access (TDMA) and is most generally utilized
of three advanced remote communication innovations (TDMA,
GSM and CDMA). GSM manages at either the 900 MHz or 1800
MHz frequency band. In this project GSM is used for getting mes-
gages for the registered mobile when leakage is detected. Even the
motor is off if the message gets to the mobile by that the repair of
the pipe can be done easily.

AT commands are instructions used to control a modem. AT is
abbreviation of Attention. In this project we use some of AT
commands they are, AT+CMGF is to set in message format for
sending to mobile. AT+CMGS is used to send SMS messages for
the registered mobile number

4. Software

The programming language used in this project is embedded C. It
is general purpose programming language we are using for ar-
duino for programming.

The main steps involved in software implementation of arduino are:
Verify, Upload, New, Open, Save and Serial.

Additional commands are also found in the software within the
menus: File, Edit, Sketch, Tools and Help

5. Implementation Results

The connections are made as per the block diagram and made a
prototype system. At first the motor will on after power is sup-
plied the water flow through pipelines from inflow of the pipeline
and the water go out through the outflow of the pipeline. Then in
LCD the inflow and outflow rate of water is displayed there will
not be much difference. If any leakage is between the pipeline
then the inflow and outflow have more value variation by that we
can know that leakage is detected and that will be displayed in
LCD. After the leakage is detected then by using GSM can get the
message to mobiles and the motor will be accordingly off so that
the water does not flow through pipeline.

The display of project board with all the connections made and
interface with arduino board is done.
The flow of water in pipeline from inflow to outflow according to the arrangement of the sensor.

The LCD display of inflow and outflow of water with unit L/H. Here we are having a little variation due to having improper arrangement to pipeline.

To show weather leakage is detected or not in pipeline we have arranged a area for leakage. When leakage is on the water leakage will be detected and motor off so that there will not be any flow of water.

As the water leakage is done in the LCD it shows that water leakage is detected

6. Conclusion

Using this system the water leakage can be detected easily and the monitoring of the water also can be done. The monitoring of water can be done by know the flow of through the pipeline during the supply. The water supplied from tank to different houses through pipelines have leakage sometimes due to that leakage there may have lot of water wastage. The controlling of water can be done by automatic off of motor when the leakage is detected in the pipeline so that the flow of water will also be off.

Acknowledgement

We are thankful to my guide who encouraged us and had faith in us. We would like to express our gratitude towards HOD, professors and entire electronics and computers science engineering department of KLEF college, Guntur for their constant support. Finally I would like to thank all the all authors whose projects
