Abstract

Are examined and defined pattern vibratory motion to form horizontal surfaces on the basis of the account of wave phenomena and bias voltages. Given numerical values screens and rheological characteristics of sealing concrete. Based on the analysis of the energy balance, motion qualities limits are defined. Analytical dependences for the estimation of main parameters of the effective vibroimpact mode are suggested as well as the motion stability layout of the analyzed system is cited.

Keywords: concrete mix, resonance, seals, vibration.

1. Introduction

In modern construction fate cast-frame method is increasingly used [1]. A large proportion of the implementation of this method is accompanied by the formation of horizontal surfaces where there is a problem of sealing. Of particular importance is the formation of horizontal surfaces in the arrangement of underground garages, units, installations and maintenance of the building etc. In this paper we solve the problem to study the dynamics of surface vehicles of considerable length (l > 2...3 m) in terms of interaction with the manufacturing environment.

2. Purpose of Work

Of surface compaction devoted a num-ber of works [2–4]. In [2, 3] considered a discrete model of the concrete mix. Signifi-cant theoretical research based on wave theory Concrete mixture ramming surface vibration are given in [4, 5], which revealed the basic laws of motion of this class of machines. The results [4, 5] is much deeper insight into the process of consolidation. Soil compaction over Vibration rammer dedicated works [6, 7]. Based on the results of the cited studies [4–7], a similar problem is solved based on the model of the envi-ronment, taking into account the shear stress [8, 9], which is one of the effective compaction.

3. Main Body

Methodology provides premise that the concrete mixture, which is under the lining for the device horizontal surfaces are quasi homogeneneous body. It is assumed that the concrete mixture is modeled flexible rod length h. Consider that at the core of the force of gravity, which causes it to longitudinal oscillations. If we denote by u(x, t) displacement of the rod cross-section of abscissa x at time t, then the differential equation of forced oscillations of "lining – a layer of concrete mix" considering energy dissipation is as follows:

\[
\frac{\partial^2 u(x,t)}{\partial x^2} + \frac{1}{c^2(1+i\gamma)} \frac{\partial^2 u(x,t)}{\partial t^2} + g, \tag{1}
\]

where \( \frac{\partial^2 u}{\partial t^2} \) and \( \frac{\partial^2 u}{\partial x^2} \) – under acceleration mixture and the second derivative of strain \( \varepsilon = \frac{\partial u(x,t)}{\partial x} \); \( i = \sqrt{-1} \), \( c \) – velocity of longitudinal waves propagating in a layer of concrete mixture having elastic modulus \( E \) and density \( \rho \), \( \gamma \) – loss factor, which characterizes the energy dissipation; \( \gamma = \frac{\Delta W}{2\pi \cdot W} \); \( \Delta W \) – energy absorbed by the basic layer of concrete mixture over period; \( W \) –potential energy of deformation of this layer; \( g \) – acceleration due to gravity.

Assuming that the concrete mix is an environment in which the generated elastic shear wave, and the surface of the lining is not separated from the surface layer of the concrete mix, the boundary conditions can be represented as follows:

\[
u|_{x=0} = 0; u|_{x=h} = x_0 \sin(\omega t), \tag{2}\]

where \( x_0 = A \) – the amplitude of oscillation of the working body lining, \( \omega \)– circular frequency of its oscillations.

We assume that the initial displacement and initial velocity is zero, then the initial conditions can be summarized as follows:

\[
u|_{t=0} = 0; \frac{\partial \nu}{\partial t}|_{t=0} = 0 \tag{3}\]
To address the problem (1) – (2) can not apply the Fourier method, since the boundary conditions (3) uniform. But this problem is easily reduced to a problem with zero boundary conditions (in which you can apply the Fourier method).

Indeed, we introduce a supporting role:

\[ w(x,t) = x_0 \sin(\omega t) - x_0 \sin(\omega t) \frac{x}{h} = x_0 \sin(\omega t)(1 - \frac{x}{h}) \]  

(4)

It is clear that:

\[ w|_{x=0} = x_0 \sin(\omega t), \quad w|_{x=h} = 0 \]  

(5)

The problem is now looking as the sum of:

\[ u(x,t) = v(x,t) + w(x,t), \]  

(6)

where \( v(x,t) \) - new unknown function. Due to the boundary conditions (2), (5) and the initial conditions (3), the function \( v(x,t) \) must satisfy the boundary conditions:

\[ v|_{x=0} = 0; \quad v|_{x=h} = 0, \]  

(7)

and initial conditions:

\[ \frac{\partial v}{\partial t} \bigg|_{t=0} = \frac{\partial w}{\partial x} \bigg|_{x=0} = 0. \]  

(8)

Substituting now equation, we get:

\[ \frac{\partial^2 v}{\partial t^2} = a^2 \frac{\partial^2 v}{\partial x^2} + g + a^2 \frac{\partial^2 w}{\partial t^2} - \frac{\partial^2 w}{\partial t^2} \]  

(9)

or by virtue of (4),

\[ \frac{\partial^2 v}{\partial t^2} = a^2 \frac{\partial^2 v}{\partial x^2} + \mathcal{R}(x,t), \]  

(10)

where,

\[ \mathcal{R}(x,t) = g - a^2 x_0 \sin(\omega t)(1 - \frac{x}{h}). \]  

(11)

In (10) and (11) introduce the notation:

\[ a^2 = c^2(1 + i \gamma). \]  

(12)

Thus, we obtain the problem for the function \( v(x,t) \):

\[ \begin{align*}
\frac{\partial^2 v}{\partial t^2} &= a^2 \frac{\partial^2 v}{\partial x^2} + \mathcal{R}(x,t), \\
v|_{x=0} &= 0; \quad v|_{x=h} = 0, \\
v|_{t=0} &= 0; \quad \frac{\partial v}{\partial x} \bigg|_{x=0} = -a\omega x_0(1 - \frac{x}{h}),
\end{align*} \]  

(13)

We will seek a solution to this problem as the sum of: \( v(x,t) = v_1(x,t) + v_2(x,t) \),

(14)

where \( v_1(x,t) \) is a solution of the inhomogeneous equation:

\[ \frac{\partial^2 v_1}{\partial t^2} = a^2 \frac{\partial^2 v_1}{\partial x^2} + \mathcal{R}(x,t). \]  

(15)

Satisfying the boundary conditions:

\[ v_1|_{x=0} = 0; \quad v_1|_{x=h} = 0, \]  

(16)

and initial conditions:

\[ \frac{\partial v_1}{\partial t} \bigg|_{t=0} = 0, \]  

(17)

\[ \frac{\partial v_1}{\partial x} \bigg|_{x=0} = 0, \]  

(18)

\[ v_1|_{t=0} = 0, \]  

(19)

Meets the boundary conditions:

\[ v_2|_{x=0} = 0; \quad v_2|_{x=h} = 0, \]  

(20)

and initial conditions:

\[ \frac{\partial v_2}{\partial t} \bigg|_{t=0} = -a\omega x_0(1 - \frac{x}{h}), \]  

(21)

Decision \( v_1(x,t) \) is the forced oscillation layer of concrete mixture, and oscillations that occur under external exciting force, if the initial perturbations are absent.

Decision \( v_2(x,t) \) is the free oscillation layer of concrete mixture, and fluctuations which occur only as a result of the initial perturbation.

Using [3], we have to \( v_2(x,t) \):

\[ v_2(x,t) = \sum_{i=1}^{\infty} a_i \cos \left( \frac{k \pi x}{h} \right) + b_i \times \sin \left( \frac{k \pi x}{h} \right) \times \sin \left( \frac{k \pi x}{h} \right) \]  

(22)

For \( v_1(x,t) \) can find a solution in the form of the following series:

\[ v_1(x,t) = \sum_{i=1}^{\infty} T_i(t) \sin \left( \frac{k \pi x}{h} \right), \]  

(23)

where
The first term in (25) is a layer of concrete mix fluctuations, caused by the presence of gravity and magnitude of the effect of the working body surface lining for placement of horizontal surfaces with zero initial conditions. The second term in (25) is a layer of concrete mix fluctuations, caused by the presence of non-zero initial conditions.

Table 2, 3 presents values $\omega_k$, $s^{-1}$ for $k = 1, 2, 3$ and different values of h, m, a, m/s.

In the case of resonance ($\omega = \omega_k$) the time during which an increase of the amplitude of the movement in the layer of concrete mix is determined by the approximate relation:

$$ t_{\text{mov.}} = \frac{2}{\gamma \omega} $$

(26)

For typical values of $\omega$ (see Tab. 1) and $\gamma = 0.1 \ldots 0.3$, $t_{\text{mov.}}$ is $(0.01 \ldots 0.02)$ s.

As a result of solving the problem of survey was requested and made screeds $l = 2$ m, $l = 3$ m and $l = 4$ m, are put into production. Specifications of screed $l = 3$ m and $l = 4$ m are shown in Tab. 2

</tbody>
</table>
The formula (33) is much simpler if you accept some conditions. For example, for $|z| >> 1$:

$$n_\delta = \frac{\gamma_\delta}{2\pi} \frac{|R|}{|z|}$$

(34)

for $|z| << 1$: in general terms $n_\delta = f(h)$.

Thus the energy balance equation can be folded in a way that limits the possible vibration amplitude will be determined by the upper – viscosity effects, and bottom – the shock dissipation. In the case under consideration, vibration resistant operation will be when $\omega_{av} = \omega$:

$$\frac{1}{2} \left( \frac{m_i + m_j}{m_j} \right) \leq q \leq \frac{1}{8\pi(n_i + n_j)(1 + R)} \xi > \frac{1}{2}$$

(35)

In the case of abruptation vibrator and mixture $\xi > 1/2$ is selected

Calculations by the formulas (35) in relation machines for seal concrete mix give range for values: $0,6 \leq q \leq 1,5$ and $1,4 \leq \xi \leq 2,5$ [7]. Thus for the criteria $q$, which determines the balance of power, the value $q = 1,0...1,5$ corresponds criteria $\xi$ which has the value $\xi = 0,8...1,3$. This is the first (Fig. 3) zone of stability, which in terms of selection parameters more suitable in certain accurately mass characteristics. This area is sensitive to changes of mass in the process of movement of the shock-vibration installation. The zone of stability at $q = 0,6...0,7$ which corresponds to $\xi = 2,0...2,5$, requires less power loss, but the amplitude spectrum may decrease, which follows from the analysis of the formula (36). Map of stability (Fig.1), built for a wide range of parameters, confirms the possible existence of several zones (at least three for installation of forming units) of stability. In Tab. 3 are shown numerical values of performance parameters of vibration-shock process to determine their effect at the time of impact $t_{imp}$.

Calculations that are made for resulted parameter values (Tab. 1) show that for the acceleration coefficient $a_{max} = (4...5)K$ at coefficient of restoration of speed $Kv = 0,3...0,4$ time of impact is equal to $t_{imp} = (0,015...0,01)\tau$, that is for the frequency, $\omega = 157\pi^{-1}$ ratio $\frac{\tau}{T} = 0,358...0,238$ which determines the effect of intense acceleration on the process of compaction. An important characteristic that affects the parameter $K_v = \tau/T$, as at the time of contact is coefficient of stiffness.

## 4. Conclusion

1. In the case of application of vibration impacts are commonly used to determine the dependence of the calculated viscosity require considerable refinement: necessary to account for vibration, and in some cases the inertial forces of resistance fluctuations.
2. To ensure that the products of good quality (horizontal surface), where the presence of cavities and shells kept to a minimum, you must set the mode vibro-formation concrete mixes, which are inherent limitations to the vibration amplitude.
3. The basic laws of motion of a concrete mixture is compacted surface lining in the process of improvement of concrete horizontal-surface, methods of mathematical physics, and held valid in terms of mathematics, the procedure for obtaining general solution of equations, allowing full use of the Fourier method.
4. Dependences should be used in the improvement and refinement of engineering calculations such systems in order to optimize them and to improve the quality furnished horizontal surfaces.
5. Formulated energy balance, realizing the impact-vibration mode mixed discrete-continuous system of movement.
6. Getting analytical dependences for definition of rational parameters of worklow and new different from main resonance, movement stable zones of contribution of higher harmonics.
