Abstract

Concrete incorporates large amount of natural resource as aggregates with cement and water. Cement production consumes huge energy and causes about 7% of total greenhouse gas emission in the world. It has been strived to provide better quality in concrete using waste by-products from industries so that natural resources are used in an efficient manner and thereby the environment is protected from waste deposits. Hence, mineral admixtures like fly ash and micro silica can be used to overcome these issues. The demand for river sand is getting increased day by day, which affects its constant supply. Under these circumstances use of quarry dust becomes inevitable. The usage of fly ash in the concrete leads to strength gain only at later stages. In order to obtain strength during the early stage, micro silica is added as a partial replacement of cement. The properties of fly ash, micro silica and quarry dust were studied. Fly ash (0-40%) and micro silica (0-15%) are used as a partial replacement for cement and quarry dust (50%) as that for river sand by mass. Mechanical properties of the concrete containing hybrid mineral admixtures and quarry dust are studied systematically.

Keywords: Fly Ash; Micro Silica; Quarry Dust; Super Plasticizer; Strength Gain Properties.

1. Introduction

Concrete plays an important role in the development of infrastructure like industrial structures, buildings, bridges and highways etc., leading to invent cement materials that are cheaper than Portland cement. Portland cement, already being a very expensive material constitutes a substantial part of the total construction cost of any project and the situation has further been aggravated by the energy crisis, which has further increased the cost of production of Portland cement. Therefore, it is of current importance for a country to explore and develop cementitious materials cheaper than Portland cement.

Industrial wastes, such as micro silica, blast furnace slag, fly ash are being used as supplementary cement replacement materials to reduce the cost as well as to control the CO₂ emission that occurs during production of Portland Cement.

Fly ash, which is also called “pulverized fuel ash” in the United Kingdom, is one of the residues produced by coal combustion, that consists of the fine particles that are discharged from the boiler with the flue gases.

Micro silica, an ultrafine powder collected as a by-product of the silicon and ferrosilicon alloy production can be used as partial replacement of cement, along with fly ash. Micro silica, which mainly constitutes amorphous SiO₂, acts as a reactive pozzolan which gives high strength and durability properties at early age, when used in concrete. It’s very translucent particles with a surface area values around 13,000 to 30,000m²/kg and the particles are roughly 100 times smaller, when compared to average cement particle. Hence, it is used to enhance the properties of concrete because of its highest fineness and rich silica content.

Quarry dust is made by crushing aggregate and segregate for required sizes to be used as a fine aggregate. During the process of crushing, the stone have irregular shapes. Due to irregular shape of the aggregates there is a better packing among the particles thereby reducing the voids in concrete. The effects of more water to binder ratio and improper compaction defects lead to undesirable properties such as honey combing, segregation, voids, capillarity, etc., which can be reduced by the use of quarry dust. Due to rough texture and angular shape of crushed stone dust the concrete becomes low workable, but on the other hand there is good bonding among the ingredients as compared to that of the conventional concrete.

The use of fly ash improves the workability of concrete. The density and air content of the concrete mix are generally unaffected with the use of fly ash. The strength gain properties of concrete decreases as the amount of fly ash increases. The rate of strength development is related to the w/c ratio and the percentage of fly ash content in the concrete mix. Modulus of Elasticity of fly ash concrete reduces with the increase of fly ash percentages. Shrinkage of fly ash concrete mix is similar to the conventional mix. RCPT test results indicate lower permeability of fly ash concrete than the conventional concrete, thus proving to be durable [1].

It was observed that fly ash substantially enhances the post-peak compressive behavior of concrete, with a comparatively smaller slope in the descending part of the stress-strain curve. Low volumes of fly ash promoted the tensile strength of concrete. High volume fly ash concrete exhibited slightly lower tensile strength, but higher values of crack tip opening displacement and final mid-span deflection in the fracture tests [2].

The usage of silica fume increased the hardened properties and modulus of elasticity of concrete for various mixes. However, the
addition of steel fiber into concrete significantly improves the toughness of high strength concrete. As the percentage of fibres is increased, the toughness also increases, which is due to the increased aspect ratio. It was also noted that the toughness of high strength fibre reinforced concrete depends on the supplementary materials like silica fume [3].

Additionally, it is well understood that silica fume, due to high pozzolanic activity, is a necessary material in producing high strength concrete. However, it also helps the concrete to have a more brittle behavior [4].

The micro silica added concrete can produce less permeable and high strength concrete. The addition of micro silica reduces the workability of the concrete. The use of micro silica increases the compressive strength and it depends on the replacement level. The tensile and flexural strength of the micro silica concrete is similar to that of the conventional concrete. Addition of micro silica increases the bond strength of concrete. The modulus of elasticity of the micro silica concrete is equal to that of the conventional concrete [5].

Micro silica, being a byproduct of the smelting process from the silicon and ferrosilicon industry, has become an attractive alternative in the utilization of industrial wastes. It was found out that silica fume affects the thickness of transition phase in mortars and the degree of the orientation of the calcium hydroxide crystals. The hydration of cement is stimulated by adding silica fume. The chloride-ion diffusion is significantly decreased and the long-term corrosion resistance is enhanced by the use of silica fume [6].

The flexural strength of concrete with 25% and 100% quarry dust were observed to be 2% and 4.3% higher than the conventional concrete respectively. Regression analysis was carried out and the empirical formulas were used to obtain the quarry dust concrete. It was also noted that the flexural strength of concrete is enhanced when quarry dust is incorporated [7].

In the present research work, the mechanical and durability properties of concrete specimens with and without fly ash and micro silica addition were experimentally assessed.

2. Experimental program

2.1. Cement

Fresh OPC 43 grade cement without any lumps was used. Testing of cement was done in accordance with IS: 8112-1989 [8]. The various tests result values of cement are given in Table 1.

Micro silica named Elkem- micro silica 920 D was used in this work, confirming to ASTM-C (1240-2000) [9]. Micro silica is utilized as a partial replacement of cement and the properties of micro silica values are given in Table 3.

2.4. Coarse aggregate

Locally available coarse aggregates having a maximum size of 20 mm were used in the present work. Testing of coarse aggregates was done as per IS: 383-2016 [10]. The various test results conducted on coarse aggregates are given in Table 4.

2.5. Fine aggregate

In the present investigation normal river sand was used as fine aggregate, which is available in Salem, extracted from Cauvery River near Musiri. The fine aggregate was screened at site to remove deleterious materials and tested as per procedure given in IS 2386 – 1963 [11]. The various test results conducted on river sand are reported in Table 5.

2.6. Quarry dust

Quarry dust passing through IS sieve 2.36 mm and conforming to grading zone II and as per IS: 383-2016 [10] was used. The properties of quarry dust values are given in Table 6.

2.7. Water

Potable tap water available in laboratory with pH value of 7 and conforming to the requirements of IS: 456-2000 [12] was used for mixing concrete and curing the specimens for various mixes of concrete.

2.8. Mix proportions

M30 grade concrete was used for the experimental works, which is being used in structural concrete in foundation works to stand against aggressive conditions. The mix design for OPC concrete was confirming to IS 10262: 2009 [13] and SP 430 and used for
all mixes of concrete. The addition of fly ash and micro silica in percentage of cement, relevant to the respective concrete mix is shown in Table 7.

| Table 7: Proportions of Hybrid Admixtures with Cement |
|-----------------|-----------------|-----------------|
| Mix ID | Cement (%) | Fly Ash (%) | Micro silica (%) |
| CC | 100 | 0 | 0 |
| F1 | 100 | 0 | 0 |
| F2 | 90 | 10 | 0 |
| F3 | 80 | 20 | 0 |
| F4 | 70 | 30 | 0 |
| F5 | 60 | 40 | 0 |
| S1 | 90 | 10 | 0 |
| S2 | 80 | 15 | 5 |
| S3 | 70 | 20 | 10 |
| S4 | 60 | 25 | 15 |

Fly ash was used as partial replacement of cement by 10%, 20%, 30% and 40% using modified replacement method. In this combination, cementitious materials were more than that used in conventional concrete. Quarry dust was used as partial replacement of river sand in conventional mix by 50% in mass. Again in each fly ash mix concrete micro silica was used as partial replacement to cement by 5%, 10%, 15% and 20% by mass at different curing days. Table 8 gives the mix proportion used in this study.

| Table 8: Mix Proportions for M30 Grade of Concrete |
|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| Mix Id | Cement (kg/m³) | Fly ash | Micro silica | Coarse aggregate | Fine aggregate | Quarry dust | w/c ratio | Super Plasticizer (%) | Slump value (mm) |
| CC | 390 | 0 | 0 | 1206 | 324 | 324 | 0.43 | 1.5 | 72 |
| F1 | 390 | 0 | 0 | 1206 | 324 | 324 | 0.43 | 1.5 | 74 |
| F2 | 351 | 39 | 0 | 1206 | 324 | 324 | 0.43 | 1.5 | 78 |
| F3 | 312 | 78 | 0 | 1206 | 324 | 324 | 0.43 | 1.5 | 79 |
| F4 | 273 | 117 | 0 | 1206 | 324 | 324 | 0.43 | 1.5 | 73 |
| F5 | 234 | 156 | 0 | 1206 | 324 | 324 | 0.43 | 1.5 | 67 |
| S1 | 351 | 39 | 0 | 1206 | 324 | 324 | 0.43 | 1.5 | 66 |
| S2 | 312 | 58.5 | 19.5 | 1206 | 324 | 324 | 0.43 | 1.5 | 67 |
| S3 | 273 | 78 | 39 | 1206 | 324 | 324 | 0.43 | 1.5 | 69 |
| S4 | 234 | 97.5 | 58.5 | 1206 | 324 | 324 | 0.43 | 1.5 | 65 |

Compressive strength of hardened concrete was measured at the ages of 7, 28 and 56 days on 150 mm cubic specimens (3 specimens in each case). The test was carried out to obtain the compressive strength by using Compression Testing Machine (CTM) of capacity 100 tons and the respective snapshot is shown in Fig. 1.

Split tensile strength on 100 × 200 mm cylindrical specimens and flexural strength on 100 x 100 x 500 mm beam specimens were tested at 28 days. The tests were carried out conforming to IS 516-1959 [14]. The prism for flexure was tested using Universal Testing Machine (UTM) of capacity 100 tons. Bond strength (pull out) test was carried out with a cylindrical specimen in which steel bar is embedded as shown in Fig. 2.

Bond stress can be calculated by using the formula:

\[ \text{Bond stress} = \frac{P}{\pi dl} \text{ (N/mm}^2\text{)} \]

Where, \( P \) = Ultimate load (N)
\( d \) = Diameter of the specimen (mm)
\( l \) = Embedded length of the specimen (mm)

Other tests such as test for modulus of elasticity (fig. 3.), water permeability test and rapid chloride permeability test were also conducted, as per standard specifications.
3. Results and discussions

3.1. Compressive strength of concrete

Results of fresh and hardened concrete containing hybrid mineral admixtures and quarry dust as a partial replacement of cement fine aggregate respectively are discussed below.

It can be noted that the F3 specimen (20% fly ash and 50% quarry dust) did not achieve the target strength at 28 days due to the delayed pozzolanic reactions. But it attains

![Fig. 4: Compressive Strength of Concrete for Various Mixes of Concrete.](image)

More strength than that of the conventional concrete at the age of 56 days. Cement normally gains its maximum strength within 28 days. During the hydration process, fly ash together with lime produced from cement hydration imparts more strength. For this reason, concrete made with fly ash will have slightly lower strength than conventional concrete at early age of concrete and subsequently attains higher strength after 56 days. Fly ash decelerates the hydration of C3S in the initial stages but accelerates it at later stages. It can be observed that the S3 mix (20% fly ash, 10% micro silica and 50% quarry dust) attains strength 33.92% greater than that of conventional concrete at the age of 56 days as shown in fig. 4. The presence of quarry dust facilitates the filling of voids between coarse aggregates in concrete and makes concrete more compact and dense, thus raising the strength of concrete. Calcium hydroxide is released when the Portland cement in concrete begins to react chemically. The micro silica reacts with this calcium hydroxide to form additional binder material called calcium silicate hydrate which is very similar to the calcium silicate hydrate formed from Portland cement. It is an additional binder that gives

![silica-fume concrete its improved properties. Hence, the use of micro silica enhances the strength of the concrete.

3.2. Split tensile strength of concrete

It can be noted that the S3 specimen (20% Fly ash, 10% Micro silica and 50% quarry dust) attains strength 51.85% greater than that of the conventional concrete as shown in Fig. 5. This is due to the fact that, through pozzolanic activity, fly ash combines with free lime to produce similar cementitious compounds formed by the hydration of Portland cement. It is due to this sequence of chemical reaction that the quantum of strength achievement for fly ash concrete is relatively slower at initial stages of curing. Moreover, micro silica dissolves in saturated solution of Ca (OH)$_2$ within few minutes, which also contributes to the strength development in concrete.

![Fig. 5: Split Tensile Strength at Different Curing Days for Various Mixes of Concrete.](image)

3.3. Flexural strength of concrete

The Ordinary Portland cement has hydrated to result in saturation of the pore water with Ca (OH)$_2$. Calcium Silicate Hydrate (C-S-H) gel is formed on the surface of micro silica particles, which
contributes to the increased strength. The test results indicate that S3 mix (20% fly ash, 10% micro silica and 50% quarry dust) attains strength of 48.28% more than that of the conventional concrete as shown in Fig. 6. Calcium silicate hydrate gel is formed from the hydration of cement, when calcium hydroxide is liberated as a result of the silica present due to the addition of micro silica.

![Graph showing flexural strength at different curing days for various mixes of concrete.](image)

**3.4. Bond strength test**

The test results indicate that the mixes F1 (50% quarry dust), F3 (20% fly ash and 50% quarry dust) and S3 (20% fly ash, 10% micro silica and 50% quarry dust) mixes attain bond strengths of 10.20%, 9.7% and 32.10% respectively at the age of 56 days. This ideology proves that these types of pozzolana when added to the cement react to form a homogeneous paste of concrete and thereby improving the bonding capacity of concrete surrounding the rebars as shown in Fig. 7.

![Graph showing bond strength of concrete for various mixes.](image)

**3.5. Modulus of elasticity of concrete test**

The experimental test results show that the young’s modulus of conventional concrete (CC), fly ash blended concrete with quarry dust (F3), concrete containing hybrid mineral admixtures along with quarry dust (S3) are $2.7 \times 10^4$ MPa, $3.0 \times 10^4$ MPa, and $3.7 \times 10^4$ MPa respectively.

The specimen containing hybrid mineral admixtures and quarry dust (S3) possess higher modulus of elasticity when compared to conventional concrete. Hence, the concrete (S3 mix) is stiffer and more durable.

**3.6. Water permeability test**

Concrete cubes of 150 mm size were cast and cured for a period of 28 days. The surface of the cubes were wiped dry and placed in the water permeability Test apparatus as per DIN 1048 Part5 (1991) [15]. The compressor was started and the pressure was applied at a rate of 0.5 MPa for...
A period of 72 hours. The specimens were later removed and split open. The actual penetration of water into the specimen was measured at three different points from the edges of the split cube and the average was found as 20% for S3 mix as shown in fig. 8.

### 3.7. Rapid chloride permeability test results

The code specifications of ASTM C 1202-97 [16]. A maximum of 1000 coulombs passed at 28 days as shown in Fig. 9. The samples were moist cured at all ages until the time of testing of concrete. RCPT was conducted on four different samples that had slight differences in the amounts of super plasticizer, fly ash, micro silica and quarry dust. It was also noted that these mixes did not reach the required 1000 coulombs passed at early age of 28 days. However, they attained the low permeability of concrete at later ages. At age of 90 days curing and later, there is almost no difference in chloride permeability among the various mixes tested.

### 4. Conclusion

The following conclusions can be drawn from experimental test results:

- From the above test results the mix S3 (Fly Ash 20% Micro silica 10% quarry dust 50%) is of higher strength than the conventional concrete.
- Addition of Micro silica increases the chemical reaction that leads to silica gel formation, which gives more strength to concrete at early ages.
- Compressive strength increases with increase in percentage of micro silica up to 10% and further increase in micro silica did not increase the strength.
- The usage of cementitious materials and quarry dust in the construction industry helps to prevent the global warming and provide optimum exploitation of the resources.
