Abstract

A solar photovoltaic panel or a solar PV module is a device, which is to be considered universality the basic constituent of a solar photovoltaic system and is a combination of series and parallel assembly of solar cells. The electrical performance of this solar photovoltaic module be contingent on different environmental situations like PV cells/module solar spectral (air mass), ambient temperature, solar irradiance, angle-of-incidence. With these dependent conditions, there will be a petite chance to operate at its maximum power point (MPP). Hence, a Perturb and Observe (P&O) MPP algorithm is employed which draws considerable power with the desired time response. In present work, the interfacing of Solar PV system with the utility grid system which is having 15kW based on the Voltage Oriented Control (VOC). The temperature of the individual photovoltaic cell and solar irradiation are to be considered as inputs for the simulation process, whereas the duty cycle of the DC-DC boost converter is an output of the P&O controller. Performance of this grid-connected PV system with VOC method is analyzed with the simulation results and %THD values of the voltage and current at coupling point is verified. The results show the superiority of VOC method and its high dynamic behavior under variable irradiation conditions.

Keywords: DC/DC Boost Converter; P&O MPPT; Grid Connected PV System; VOC; VSI.

1. Introduction

Past few decades the fossil fuels take a vital role with his major contribution in power generation. It is always an important that energy issue for the development of country and also relation in between inter and intra countries, and present era it become priority concept because of the aware about the limitations of present traditional energy sources like coal and petroleum and also the negative climate impacts and demerits of using fossil fuels and it becomes insufficient to meet the gradual increase of the load demand [2]. Due to the increasing load demand and lack of resources, the future focus is towards research and development of alternative energy sources, in order to survive from the energy crisis many industries and government encouraging with different attractive schemes towards the alternative energy source. With free availability of renewable energy resources it is identified that the important alternatives are air, water and solar photovoltaic (PV). Within these three, again the solar PV is chosen as a best one irrespective of the location and nature of loads. It attains important due to a lot of research is done on PV system and converter technology with power semiconductor devices with reduced cost, size and increased performance [3]. But in the large-scale installation of the PV system has a major disadvantage due to its initial cost and low conversion efficiency [4]. every solar PV panel has multiple current-voltage characteristics each of the different combinations of conditions that would affect the STC such as temperature, air mass, irradiance and at every characteristic curve the maximum power point will differ and need to track this maximum PV power output [5]. The different maximum power point harvesting techniques are used to find the MPP and are listed in [6], and are shown in below fig 1.

![Fig. 1: Classification of Various MPPT Methods [6].](image)

Among the above techniques, the universally accepted method of obtaining MPP is the Perturb and Observer (P & O) [7–10]. In present paper pays under all the possible conditions the conventional P&O method tracks the maximum power irrespective of the system operating conditions. Along with the P&O, the VOC based control technique is employed for the enhancement of the efficiency of
grid-connected solar PV system. In this present work, it is divided into five different sections, description about the grid-connected PV system by section II, whereas section III will be the complete characteristics and the sizing of the PV array which is considered is given, and the clear explanation of MPPT based P&O algorithm are in section IV, and the results are given in section V, finally the conclusion will summarizes a idea of the present work.

2. System description

At standard test conditions (STC) the PV array in the proposed paper generates a maximum power of 15kW. Each module of 305W is employed for the creation of the array. Each module contains 96 cells. These modules are arranged in such a manner that a total of 15kW energy is generated from the solar irradiation. A total of 5 series and 10 parallel modules are connected (5*10*305=15250W≈15kW). The detailed specifications of the solar PV module which is selected are mentioned in Table 1. From the schematic diagram (Fig 2) representation, the first block PV array has only one input that allows unpredictable (continuous changing) sun irradiance (in W/m²) and temperature (°C) is chosen as constant. For the simulation process, the irradiance profile is defined by a Signal Builder block as input for the PV array. The current-voltage and Power-voltage characteristics of the single module with below specifications mentioned in table 1 are shown in Fig. 3, and the I-V and P-V characteristics of a total array are shown in Fig. 4.

Table 1: Specifications of the Solar Module

| Total number of solar cells in Panel/module | 96 |
| Open Circuit Voltage (in Volts) (V_{oc}) | 64.20 |
| Short Circuit Current (in Amps) (I_{sc}) | 5.96 |
| Voltage at MPP (in Volts) (V_{MPP}) | 54.70 |
| Current at MPP (in Amps) (I_{MPP}) | 5.58 |
| Power at MPP (in Watts) (P_{MPP}) | 305.226 |

3. MPPT control strategy

The P&O algorithm which is employed in [5] is used here for the generation of the pulses for the boost converter. The Fig 5 shows the flowchart of the P&O algorithm. The irradiance, duty cycle generated from the algorithm is shown in Fig. 6. In Fig. 6, it can be observed that the duty cycle is controlled with the output of the voltage and currents of the PV array. The top trace in Fig. 6 is the irradiance value and the bottom trace is generated duty cycle for the boost converter (DC-DC).

4. Discussion and simulation results

The grid-connected PV system is employed beneath both fast and slow alteration of environmental situations (variable irradiance) with the constant ambient temperature is maintained, this can be observed in the top trace of the Fig.6. The results of the grid-connected PV system are explained in three different stages. In the first stage, the irradiation is increased from minimum to maximum. The results for this stage are shown in Fig 7. The top trace shows the irradiation it is increased from 600W/m² to 1000W/m². During this time the PV array voltage, current and power are shown in Fig 7. whereas in Fig 8, in the top trace, it is observed that a constant value of the DC voltage is obtained from the DC-DC converter and is fed to the voltage source inverter for the conversion of the DC into AC. A two-level voltage waveform can be observed in the second trace in Fig.8. The three phase voltage, current waveforms for feeding into the grid is shown in Fig 9. During the grid fed inversion it is required to maintain near to unity power factor this can be seen in Fig 10. i.e., the voltage and current both in the same phase only. The active and reactive powers fed to the grid are also shown in Fig 11. All these results are shown for the non-uniform incremental irradiation values.

In the second stage, the irradiation is maintained constant. The results for this stage are shown in Fig 12. The top trace shows the irradiation it is maintained at 1000W/m². During this time the PV array voltage and currents are presented in Fig 12. In Fig 13, the top trace is identified that a constant value of the DC voltage is obtained from the DC-DC converter and is fed to voltage source inverter for the conversion of the DC into AC. A two-level voltage waveform can be observed in the second trace in Fig 13. In Fig 14, the grid fed three-phase voltage and currents can be seen. During the grid fed inversion it is required maintain the unity power factor this can be seen in Fig 15. i.e., the voltage, current both are in the same phase only. The active and reactive powers fed to the grid are also shown in Fig 16. All these results are shown for the constant irradiation values.
In third stage, the irradiation is decreased from maximum to minimum. The results for this stage are shown in Fig 17. The top trace shows the irradiation it is increased from 1000W/m² to 600W/m². During this time the PV array voltage and currents are presented in Fig 17. In Fig 18., the top trace it is observed that a constant value of the DC voltage is obtained from the DC-DC converter and is fed to the voltage source inverter for the conversion of the DC into AC. A two-level voltage waveform can be observed in the second trace in Fig 18. In Fig 19. The grid fed three-phase voltage and currents can be seen. During the grid fed inversion it is required to maintain near to unity power factor this can be seen in Fig 20. i.e., the voltage and current both in the same phase only. The active and reactive powers fed to grid are also shown in Fig 21. All these results are shown for the non-uniform incremental irradiation values.

Fig. 23: %THD of Grid Fed Current.
5. Conclusion

In the present work, Voltage Oriented Control (VOC) based MPPT solution in order to interconnect the solar PV system of 15 kW with the utility grid is presented and the results are discussed. The P&O algorithm is used for obtaining MPP from the PV array. The simulation results and %THD values of voltage and current at coupling point show the effectiveness of conventional P&O algorithm with VOC an effective interface is possible with the utility grid. And the results have shown the superiority of VOC method and its high dynamic behavior under variable irradiation conditions. Various PWM algorithms can be employed to reduce %THD is the further scope of this work.
