Abstract

The article deals with several species of the cruciferous family (Cruciferae Juss.): headed cabbage (Brassica oleracea L.), turnip cabbage (Brassica rapa L.), cultivated radish (Raphanus sativus L.), horse radish (Armoracia rustica Gaerth.-Mey-Scherb.), Italian asparagus, or broccoli (Brassica oleracea L.), turnip cabbage (Brassica rapa L.), and others. It has been determined how many micro- and macroelements, as well as fat- and water-soluble vitamins they contain. The phytochemical research has been conducted in the Food Safety and Quality Assessment Laboratory of the Almaty Technological University. The photochemical analysis of the species concerned has been carried out in accordance with GOST 25555.3-82, GOST 30417-69, and M-04-41-2005.

Keywords: Flower, seeds, beans, glucoside, photochemical analysis, macroelements, microelements, lentil.

1. Introduction

The cruciferous family (Cruciferae Juss.), also called the cabbage family (Brassicaceae), includes annual or perennial herbs, and, in some cases, shrubs. There are 3,200 species belonging to 350 genera spread mainly across the Northern Hemisphere of the world. In Kazakhstan, there are 298 species belonging to 78 families. Most often, species of this family grow in the temperate zone, mainly in mountainous areas, as well as in tropical forests. Their leaves are located alternately or in a rosette. They bloom from March to August. They have sprawling flowers, which can be white, pink, yellow, blue. Flowers can be bisexual with four sepals arranged against one another. One pistil, six stamens, two of which are short and four of which are long. Their fruits are pods or the so-called silicules. Their seeds contain vegetable oils, as well as glucosides. These plants include vegetable, fodder, medicinal, household and honey species. The vegetable products of the cabbage, or cruciferous family (cabbage, turnip, radish, mustard, horseradish, etc.) are used as dyes (winter cress, woad). Some species are used in the beauty industry, as well as in honey production. Food species are headed cabbage (Brassica oleracea L.), cultivated radish (Raphanus sativus L.), and brown mustard (Brassica juncea L.).

Some fodder species of the cruciferous family growing in the desert regions of Kazakhstan are rare species and are included in the Red List of Kazakhstan. Fifteen plant species of this family are under protection: Arabis popovii Botsch.Ved., Strogranovia robusta Pavl., Stubendorfia gracilis Botsch. Evved., and others.

Subject matter of the research: Family: Crucifers (Cruciferae Juss.). Species: headed cabbage (Brassica oleracea L.), turnip cabbage (Brassica rapa L.), cultivated radish (Raphanus sativus L.), horse radish (Armoracia rustica Gaerth.-Mey-Scherb.), broccoli, or Italian asparagus (Brassica oleracea L., or Brassica oleracea L.).

Purpose of the research: To determine the content of water- and fat-soluble vitamins, as well as macro- and microelements in the plants of the cruciferous family (Cruciferae Juss.) grown on vegetable farms of the Almaty Region.

2. Materials and Methods

The phytochemical research has been conducted in the Food Safety and Quality Assessment Laboratory of the Almaty Technological University. The photochemical analysis of the species concerned has been carried out in accordance with GOST 25555.3-82, GOST 30417-69 and M-04-41-2005.

3. Discussion

Headed cabbage (Brassica oleracea L.). It is a biennial cultivated plant of the cruciferous family (Figure 1). It has a stout and well-branched root system. The headed cabbage comes from the Mediterranean coast, Ancient Greece. In Russia, the headed cabbage appeared much later. Ancient manuscripts referring to the cabbage date back to 1073. Consuming 200 g of cabbage every day prevents cold and improves digestion, as well as protects people against vitamin C deficiency. The cabbage also contains the antirucer vitamin U which helps treat this rare digestive disease. Al. Eskendirov determined the composition of the cabbage (1982); A. Nisambev found that the cabbage contained vitamin U (1990) [1, 2]. The phytochemical analysis determined the amount of vitamins, as well as the quality and quantity of mineral...
elements. Cruciferous species contain some mineral elements such as sulfur, phosphorus, calcium, potassium, and chlorine. According to the research findings, the content of Ca was 7.12 mg per 100 g, Mg = 31.57 mg per 100 g, and Fe = 16.9 mg per 100 g. The vitamin content was as follows: vitamin E = 0.06 mg per 100 g, vitamin C = 0.038 mg per 100 g, B1 (riboflavin) = 0.016 mg per 100 g, B6 (pyridoxine) = 0.0096 mg per 100 g, B3 (pantothenic acid) = 0.0053 mg per 100 g, and B5 (nicotinic acid) = 0.0021 mg per 100 g.

The turnip cabbage (Brassica rapa L.) is a biennial herbaceous plant of the cabbage family (Figure 2). It is edible, and its root vegetable is white or yellow. In its first year, the plant gains its leaves and a thick root vegetable, and in its second year, it blooms and bears its fruit. It has sprawling flowers, which are red and yellow or yellowish. Its fruits are pods. The turnip cabbage is pollinated by insects, and it is resistant to cold and prefers moist environment. It grows well at a temperature of 12 to 20°C. Vegetation period is 60 to 85 days. The turnip grows well in clay and sandy soil. Its seeds are planted in spring [3]. According to the research findings, the content of Ca in turnip cabbage fruit was 8.67 mg per 100 g, Mg = 21.3 mg per 100 g, and Fe = 5.8 mg per 100 g. The vitamin content was as follows: no vitamin E was found; vitamin C = 0.044 mg per 100 g; B2 (riboflavin) = 0.012 mg per 100 g; B6 (pyridoxine) = 0.0049 mg per 100 g; no B1 was found; and no B5 was found.

Cultivated radish (Raphanus sativus L.). It is a biennial plant resistant to cold, member of the cabbage family (Figure 3). In its first year, the plant gains its leaves and a thick root vegetable, and in its second year, it blooms and bears its fruit. It has sprawling flowers, and it is cross-fertilized. Its fruit are pods. It can be easily hybridized with the annual cultivated radish, as well as the wild radish (garden radish) (Raphanus sativus L. Var. Radicula). It is grown in all the CIS regions. Its root, which is its fruit, is used as food and sometimes in pharmaceutical manufacturing. The cultivated radish (the black radish) has some antibacterial properties and helps restore the production of gastric juice [4, 5]. Some varieties of the cultivated radish ripen late (in autumn), and some ripen early. The best varieties of the radish are as follows: Gravvoronskaya radish (with an oval white root vegetable), winter black radish (with a round root vegetable; black outside and white inside), winter white radish (with a white root vegetable and a bitter taste), local Dungan radish (with a round or elongated root vegetable and a bitter taste), etc. [6]. According to the research findings, the content of Ca in radish fruit was 7.82 mg per 100 g, Mg = 26.31 mg per 100 g, and Fe = 20.1 mg per 100 g (Table 1). The vitamin content was as follows: no vitamin E was found; vitamin C = 0.089 mg per 100 g; B2 (riboflavin) = 0.013 mg per 100 g; B6 (pyridoxine) = 0.038 mg per 100 g; vitamin B3 = 0.0049; and vitamin B5 = 0.00041 (Table 2).

White mustard (Sinapis alba L.). It belongs to the cruciferous family (Figure 4). Some seeds are used in pharmaceutical manufacturing. The plant blooms in June and July, and it is an annual herbaceous weed growing in the fields of southern and central former USSR countries. Its green seeds are sown as animal feed and raw material for flour and oil production. Mustard seeds contain up to 35 to 47 % fat [7].

Hors eradish (Armoracia rutaecarpa Gaerth.-Scherb.). It is a perennial plant of the cruciferous family (Figure 5). It is sown in all regions of Kazakhstan. One of its species – the horseradish – grows in fields and vegetable gardens as a wild plant. It is grown in many regions of Kazakhstan. The height of the horseradish is about one meter. Its trunk is straight, and its top is branched. It has a white fragrant flower. It blooms in June and it is propagated.
vegetatively [8]. It is resistant to cold. Its root and leaves contain potassium, sodium, phosphorus, iron, chlorine, copper, essential oils, vitamin C, phytocides, lysozymes, etc. The roots and green leaves of the plant are used in preservation and salting of cucumbers, tomatoes, and mushrooms. The horseradish is used to treat lumbar radiculitis, diseases affecting muscles, back and lumbar region, as well as rheumatism and joint diseases. Its leaves are used as a bandage applied to various wounds [9]. According to the research findings, the content of Ca in the plant is 11.17 mg per 100 g, Mg = 87.4 mg per 100 g, and Fe = 25.01 mg per 100 g. Vitamin content is the following: no vitamin E was found; no vitamin C was found; B2: (riboflavin) = 0.013 mg per 100 g; B3 (pyridoxine) = 0.0044 mg per 100 g; vitamin B1 = 0.0029; and vitamin B5 = 0.00025 mg per 100 g.

**Broccoli, or Italian asparagus (Brassica oleracea, or Brassica sylvestris).** It is an annual species of the cabbage family (Figure 6). In its first year, its stem reaches 60 to 90 cm in height and forms multiple succulent branches (peduncles) on the top ending with dense groups of small green buds. The best environment for the broccoli is cool damp climate with a temperature of 18 to 23°C. When its buds become bright yellow, it means that the broccoli is overripe and not suitable for consumption [10, 11]. The plant is rich in microelements, especially vitamins C and K. In its vitamin A content, it prevails over all other types of cabbage. According to the research findings, the content of Ca is 9.83 mg per 100 g, Mg = 33.24 mg per 100 g, and Fe = 17.8 mg per 100 g. Vitamin content is the following: vitamin E = 0.94 mg per 100 g; vitamin C = 0.017 mg per 100 g; B2 = 0.013 mg per 100 g; B6 = 0.005 mg per 10(11,9),(991,992)
4. Conclusion

As the research shows, the content of Ca in the horseradish (Armoracia Gaerth.-Mey-Scherb.) amounts to 11.17 mg per 100 g, which is much higher than the content of this microelement in the other types of cruciferous plants described in the article. The lowest content of Ca (7.12 mg per 100 g) has been found in the headed cabbage (Brassica oleracea L.). The horseradish (Armoracia Gaerth.-Mey-Scherb.) also has the highest content of Mg (87.4 mg per 100 g), and as for the turnip cabbage (Brassica rapa L.), it has the lowest content of this microelement compared to the other species – 21.3 per 100 g. The highest Fe content (25.01 mg per 100 g) has also been found in the horseradish samples (Armoracia Gaerth.-Mey-Scherb.), and the turnip cabbage (Brassica rapa L.) has again showed the lowest Fe content (5.8 mg per 100 g). No vitamin E has been found in some of the species, such as the turnip cabbage (Brassica rapa L.), and horseradish (Armoracia Gaerth.-Mey-Scherb.), and broccoli, or Italian asparagus (Brassica oleracea, or Brassica sylvestris). A high amount of vitamin B₆ (0.0096 mg per 100 g) is contained in the headed cabbage (Brassica oleracea L.), while the broccoli (Brassica oleracea) does not contain much of it – just 0.005 mg per 100 g. No vitamin B₉ has been found in the headed cabbage (Brassica rapa L.), broccoli, or Italian asparagus (Brassica oleracea, or Brassica sylvestris). No nicotinic acid (vitamin B₁) has been found in the turnip cabbage (Brassica rapa L.), Folic acid (B₉) is contained in the broccoli, or Italian asparagus (Brassica oleracea, or Brassica sylvestris) in the amount of 0.00055 mg per 100 g, and it has not been found in the other four types of cruciferous species considered in the article.
