Abstract

In this paper, the third grade non-Newtonian MHD blood flow in the porous arteries subjected to the periodic pressure gradient was studied using the Caputo-Fabrizio (NFDt) time fractional order derivative. The time fractional model was solved by taking the Laplace and the finite Hankel transforms. Results were compared with those reported in the previous studies and good agreement was found. The Mathematica software was used to simulate the velocity profile and the Bessel functions with zero order and first order of first kind. The correlations between the flow velocity and the third grade non-Newtonian fluid parameter, the magnetic field and the porosity were negative. Nevertheless, the flow velocity increased with respect to the Womersley number.

Keywords: Caputo-Fabrizio fractional derivative, Incompressible fluid, Unsteady pulsatile.

1. Introduction

Blood flows inside human arteries consist of red blood cells (RBCs), white blood cells (WBCs), platelets and other nutrients. Blood serves as a carrier in transporting water, glucose, minerals and other necessary materials, etc. to organs. Several artery properties such as wall porosity, wall elasticity and phase angle could affect the blood flow behavior. RBC is rich in iron; therefore, its properties of blood and magnetic particles were low in the presence of external magnetic field. However, both velocities increased when the Reynolds number decreased. According to Akbar [2], for symmetric stenosis, the resistance caused by impedance reaches to its maximum value, and due to high flow rate in the diverging tapered artery it was smaller than as compared to the converging tapered artery case and size of the trapping bolus was increased by increasing the height of the stenosis $\delta$ and $n$, while the number and size of the trapped bolus was decreased in the non-tapered artery $\phi > 0$ and converging tapered artery $\phi < 0$ than as compared to the diverging tapered artery $\phi > 0$. Akbar and Nadeem [3] found that by simply increasing the Weissenberg number, the fluid velocity increased and the impedance resistance decreased. The flow velocity in the converging tapered artery was higher than those in the non-tapered and diverging tapered arteries. Also, by increasing $m$, $n$ and $L$, the resistance to impedance increased for all arteries. In Akbarzadeh [4] reported that, the effect of viscous forces on blood flow was more evident at low Womersley number; all velocity plots were parabolic in shape and oscillation of flow velocity was found due to the pressure gradient. Furthermore, in the presence of high pressure gradient, the velocity remained constant at the extreme positions and it was higher in the core region. Akinshilo and Sobamowo [5] have established various MHD fluid flow models, by taking into account the thermophoresis parameters and viscosity. Their results were useful for the treatment of blood-related diseases by improving the drug delivery mechanism and the blood transportation in the porous medium via nano particles. According to Bao et al [6], their non-contact technique (in which the free surface flow of liquid oxygen was controlled by employing the non-uniform magnetic field) could develop the interface renewal and, minimize the resistance of flow inside the cryogenic distillation column by refining the flow uniformity, (more effective than air separation of cryogenic). According to Das [7] highlighted that increased viscoelastic parameter would decrease the flow velocity. However, by increasing the porosity and the mass Garashof number, the flow velocities of both Newtonian and non-Newtonian fluids increased significantly. The effect of viscoelastic parameter on wall shear stress was more evident than those on temperature and concentration profiles. Eldosoky [8] reported that both channel temperature and axial blood flow velocity increased with respect to the Prandtl number and the heating source parameter. However, these parameters decreased as, the decay’s parameter increased. The normal blood flow velocity decayed as the Prandtl number and the heating source parameter increased. The results were useful for physiological fluid! dynamists and medical practitioners. The temperature variation in the radial direction was marginal as reported by Fardad et al [9], however, it had a pseudo parabolic propensity upon normalization. Gupta et al [10], highlighted that the wall shear stress in the irreg-
2. Formulation of the problem

The unsteady pulsatile laminar MHD flow of the third grade incompressible non-Newtonian fluid inside the porous artery was analyzed. The problem domain in the cylindrical coordinate systems \((r, \phi, z)\) was shown in Figure (1). As seen, blood flows in the \(x\)-direction through a porous artery of radius \(R\). The axial blood flow velocity \(u(r, t)\). The fluid flow was axisymmetric. On the outer wall (i.e. \(r = R\)), the no-slip condition \((u = 0)\) was assumed. Due to the pumping action of heart, the pressure gradient was included to simulate the pulsatile blood flow inside the porous artery.

\[
- \frac{\partial p}{\partial x} = \frac{A_0}{g} f_p^{1/2} \cos(\omega_p t) \cos(\omega_p t + \vartheta). \tag{1}
\]

In (1), \(A_0\) is the steady part and \(A_1\) is the amplitude of the pressure fluctuation that gives rise to the systolic and diastolic pressures, \(\omega_p = 2\pi f_p\) is the frequency of the heart pressure, and \(f_p\) is the frequency of the pulse rate. Furthermore, \(g(t)\) represents the body acceleration, \(A_g\) is the acceleration amplitude, \(\omega_g\) is the frequency, and \(\vartheta\) is the angle between the body acceleration and the pressure gradient. The effect of gravity was neglected.

![Flow pattern](image)

The governing momentum equation in the axial direction (Akbarzadeh [4]) can be written as:

\[
\rho \frac{\partial}{\partial t} u(r, t) = -\frac{\partial p}{\partial x} \{\text{div} \tau\}_x - \frac{\mu}{K} u(r, t) - \frac{\rho A_g}{g^{1/2}} \cos(\omega_g t + \vartheta) - \rho B_0^2 \tau u(r, t). \tag{2}
\]

where \(\tau = \rho I + [\mu + \beta(t A_1^2 r)] A_1 A_2 + \alpha_1 A_2 + \alpha_2 A_1^2\). \(\tau\) is the stress tensor, \(\rho\) is the pressure, \(K\) is the porosity parameter, \(\mu\) is the blood viscosity, \(\rho\) is the blood density, \(\sigma B_0^2\) is the magnetic parameter, \(t\) is the time, \(\alpha_1, \alpha_2\) and \(\beta\) are the material moduli, and \(A_1\) and \(A_2\) are the Rivlin Ericksen or kinematical tensors.

\[
\begin{align*}
A_1 &= \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & \frac{2}{\rho} & \frac{1}{\rho} & 0 \\ 0 & 0 & 0 & 0 & 0 \\ \frac{2}{\rho} & \frac{1}{\rho} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \\
A_2 &= \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}
\end{align*}
\tag{3}
\]

The non-dimensional variables are:

\[
\begin{align*}
\tau' &= \frac{r}{R} \tau', \\
u' &= \frac{u}{u_n}, \\
u' &= \frac{\omega_g}{2\pi}
\end{align*}
\tag{4}
\]
The dimensionless form of the momentum equation (2), can be written as,

\[ \zeta^2 \frac{\partial^2 u}{\partial t^2} = B_1 (1 + \gamma \cos 2\pi\tau) + \left( \frac{1}{r} \frac{\partial}{\partial r} u(r,t) + \frac{\partial^2}{\partial r^2} u(r,t) \right) + \Lambda \left( \left( \frac{1}{r} \frac{\partial}{\partial r} u(r,t) \right)^3 + 3 \frac{\partial^2}{\partial r^2} u(r,t) \left( \frac{\partial}{\partial r} u(r,t) \right)^2 + B_2 \cos(2\pi s) \right) - (M^2 + P) u(r,t), \]  

(5)

The Caputo-Fabrizio time fractional model of order \( \alpha \) of (5) such that \( \alpha \in (0,1) \) obtained by taking \( \frac{\partial}{\partial t} = D^{(\alpha)} \),

\[ \zeta^2 D^{(\alpha)} \frac{u(r,t)}{u(r,t)} = B_1 (1 + \gamma \cos 2\pi\tau) + \left( \frac{1}{r} \frac{\partial}{\partial r} u(r,t) + \frac{\partial^2}{\partial r^2} u(r,t) \right) + \Lambda \left( \left( \frac{1}{r} \frac{\partial}{\partial r} u(r,t) \right)^3 + 3 \frac{\partial^2}{\partial r^2} u(r,t) \left( \frac{\partial}{\partial r} u(r,t) \right)^2 + B_2 \cos(2\pi s) \right) - (M^2 + P) u(r,t), \]  

(6)

where \( \zeta^2 = \frac{\rho_0 R^2}{2\mu \nu} \) is the dimensionless Womersley number, 
\( \gamma = \frac{A_0}{A_1} \) and \( \Lambda = \frac{2 \beta U_{\infty}^2}{\mu R^2} \) are the third grade non Newtonian fluid parameters, \( B_1 = \frac{A_0}{\mu U_{\infty}} \) represents the pressure gradient, 
\( M^2 = \frac{\sigma B_0^2}{\mu} \) is the magnetic field parameter, and \( B_2 = \frac{\rho A_0 R^2}{\mu U_{\infty}} \)

shows the acceleration parameter. The, frequency ratios can be represented as \( \omega = \frac{\alpha_0}{\alpha_\nu} \) and \( \frac{B_2}{B_1} = \frac{\rho A_0 R^2}{\mu U_{\infty}} \).

Furthermore,

\[ D^{(\alpha)} f(t) = \frac{M(\alpha)}{1 - \alpha} \int_0^t f(t) \frac{d}{d\tau} \tau^{(1-\alpha)} \, d\tau, \]  

(7)

with \( \alpha \in [0,1], \alpha \in (-\infty,0) \), and \( f \in L^1(a,b), b > a \) where \( L^1(a,b) \) is the class of all integrable functions \( f \) on \( [a,b] \). \( M(\alpha) \) is the normalization function such that \( M(0) = M(1) = 1 \). In the current paper, the condition \( \alpha \in (0,1) \) was followed strictly in order, to have a better understanding on the problem of the non-local model. For \( \alpha = 1 \), the non-locality was lost. The non-dimensional initial and boundary conditions can be written as:

\[ u(r,0) = 0, \quad \frac{\partial}{\partial r} u(r,t)|_{r=0} = 0, \quad u(1,t) = 0, \]  

(8)

3. Solution to the problem

The new definition of Caputo–Fabrizio fractional derivative (NFD) assumes two different representations for the temporal and spatial variables. The first representation works on time variable. In this situation it is more convenient to use the Laplace transform. By applying the Laplace transform on the temporal variable \( t \) given in (6) and imposing the boundary conditions given in (8):

\[ \zeta^2 \tilde{u}(r,s) = B_1 \left( 1 + \frac{\gamma}{s^2 + 4\pi^2} \right) + \left( \frac{1}{r} \frac{\partial}{\partial r} \tilde{u}(r,s) + \frac{\partial^2}{\partial r^2} \tilde{u}(r,s) \right) + \Lambda \left( \frac{1}{r} \frac{\partial}{\partial r} \tilde{u}(r,s) \right)^3 + 3 \frac{\partial^2}{\partial r^2} \tilde{u}(r,s) \left( \frac{\partial}{\partial r} \tilde{u}(r,s) \right)^2 - (M^2 + P) \tilde{u}(r,s) + B_2 \frac{s \cos \theta - 2 \mu \sin \theta}{s^2 + 4\pi^2 \omega^2} \]  

(9)

\[ \tilde{u}(r,0) = 0, \quad \frac{\partial}{\partial r} \tilde{u}(r,s)|_{r=0} = 0, \quad \tilde{u}(1,s) = 0 \]  

(10)

Here \( \tilde{u}(r,s) = \mathcal{L}[u(r,t)] \). The dimensionless governing Caputo–Fabrizio time fractional model contains highly non-linear terms with respect to the radial component \( r \). By taking the finite Hankel transform of order zero with respect to the radial coordinate \( r \) of (9) and applying the boundary conditions in (10)

\[ \tilde{u}_{H}(r_n, s) \left[ \zeta^2 \frac{s}{s + \alpha(1-s)} + r_n^2 (\Lambda + 1) + M^2 + P \right] = J_l(r_n) B_1 \left( 1 + \frac{\gamma}{s^2 + 4\pi^2} \right) + B_2 \left( \frac{s \cos \theta - 2 \mu \sin \theta}{s^2 + 4\pi^2 \omega^2} \right) \]  

(11)

where \( \tilde{u}_{H}(r_n, s) = \mathcal{H}[\tilde{u}(r, t)] \), \( r_n \) for \( n = 1,2,\ldots \), are the positive roots of the equation \( J_l(s) = 0 \), which is the Bessel function of first kind and zero order. Eq. (11) can be written explicitly for \( \tilde{u}_{H}(r_n, s) \) as

\[ \tilde{u}_{H}(r_n, s) = J_l(r_n) \frac{B_1}{a_n} \left[ \frac{s}{s + a_n} + \frac{\gamma}{s + a_n} \times \frac{s}{s^2 + 4\pi^2} + \frac{\alpha_3}{s + a_n} + \frac{\alpha_3}{s + a_n} \times \frac{s}{s^2 + 4\pi^2} + \frac{B_2}{s^2 + 4\pi^2 \omega^2} \right] \]  

(12)

3.1. Axial velocity

By applying the inverse Laplace transform \( L^{-1} \) on (12) and using the Robotnov/Lorenzo \( F_q[a, t] \) function defined as:

\[ L^{-1} \left( \frac{1}{s^q - a} \right) = F_q[a, t] = \sum_{n=0}^{q} \binom{q}{n} a^{n+1} t_{q-n}, \]  

(13)

One obtains

\[ u_{H}(r_n, t) = J_l(r_n) \frac{B_1}{a_n} \left[ \frac{1}{s + a_n} \times e^{-\alpha_3 t} \right] \left[ \cos(2\pi \omega t + \theta) + a_n^2 e^{-\alpha_3 t} \right] + B_2 \left[ -a_n e^{-\alpha_3 t} + \cos(2\pi \omega t + \theta) \right] \]  

(14)
By inverting the Hankel transformation in (14), the final expression for axial velocity, which has two Bessel functions with zero and first order of first kind, can be retrieved.

\[ u(r, t) = 2 \sum_{n=0}^{\infty} J_0(r \tau_n) J_1(\tau_n) t, \quad (15) \]

\[ u(r, t) = 2 \sum_{n=0}^{\infty} J_0(r \tau_n) \left[ B_1 \left(-\gamma a_{n2} e^{-\alpha \omega t} \cos(2 \pi t) + a_{n3} e^{-\alpha \omega t} \cos(2 \pi t) \right) \right]_n \]

\[ + B_2 \left(-a_{n2} e^{-\alpha \omega t} \cos(2 \pi t + \beta) + a_{n3} e^{-\alpha \omega t} \cos(2 \pi t + \beta) \right) \]

\[ (16) \]

The axial flow velocity in the domain of interest can be determined via (16). In (14) and (16), \( f \ast g \) represents the convolution product of \( f \) and \( g \). The parameters used in evaluating the simulation results are:

\[ a_{n1} = M^2 + \rho n_2 (1 + \Lambda), \quad (17) \]

\[ a_{n2} = \frac{a_{n1} \alpha}{a_1 + a_{n1} - a_1 \alpha}, \quad (18) \]

\[ a_{n3} = \frac{\alpha}{1 - \alpha}, \quad (19) \]

\[ a_{n4} = \frac{a_{n1} a_{n3}}{a_{n2}}, \quad (20) \]

4. Results and discussion

The main aim of the current study was to apply the Caputo-Fabrizio fractional derivative NFD for MHD blood flow simulation. The time fractional model was solved using Akbarzadeh [4], \( \alpha = 1 \) was taken and the governing equations were solved using the local model. As shown in the Table 1, good agreement was found. The fluid velocity \( u(r, t) \) in the \( x \)-direction obtained from (16) was then examined by manipulating the values of Womersley number \( \zeta \), third grade non-Newtonian parameter \( \Lambda \), magnetic field parameter \( M \) and porosity parameter \( P \). The axial and radial velocity \( u(r, t) \) profiles were plotted for \( \alpha \in [0.2, 0.3, 0.5] \) (see Figures (2-15)). In these plots the following parameters were prescribed: \( B_1 = 1.4, B_2 = 1.44, \gamma = 0.2, \omega = 1, \quad \beta = \frac{\pi}{24} \) and \( t = 1.939 \).

By increasing the strength of the external magnetic field, the radial flow speed decreased. Therefore, by simply controlling the external magnetic field, the axial blood flow velocity can be adjusted accordingly. The effect of the intensity of external magnetic field on the blood flow velocity was depicted in Figures (2-4). Moreover, the velocity variation was large at higher fractional parameter \( \alpha \).

Figures (5-7) show the influence of the third grade parameter \( \Lambda \) on the flow behavior. As seen, the amplitude of the velocity profile decreased as the third grade non-Newtonian parameter \( \Lambda \) increased, which was consistent to that reported by Akbarzadeh [4]. The effect of Womersley number \( \zeta \) (ratio of transient inertial to viscous forces) on the axial velocity was depicted in Figures (8-10). At large \( \zeta \), the velocity profile was parabolic, indicating that the fluid was dominated by the inertial forces. At small \( \zeta \), the velocity decreased with respect \( r \), (viscous dominated). However, for large \( \zeta \), a small variation was observed when the fractional parameter \( \alpha \) approached null. The correlation between the permeability parameter \( P \) and the velocity was negative as shown in Figures (11-13) due to the porous nature of the channel or artery. This observation is helpful in surgeries.

5. Conclusion

The pulsatile blood flow inside the porous arteries was simulated by applying exerting the periodic pressure gradient (simulating the presence of an external magnetic field). The Caputo-Fabrizio (NFD) time fractional order derivative was adopted. The blood was modeled as the third-grade non-Newtonian fluid. The time fractional model was solved by first taking the Laplace transformation, followed by the finite Hankel transformation (coupled with the Lorenzo function). The governing time fractional model was solved in the non-local system. The relationship between the velocity and the \( \alpha \) value was investigated for various flow parameters. The correlation between the velocity and variables such as the visco-elastic, the magnetic field and the porosity parameters were negative. Nevertheless, the velocity increased with respect to the Womersley number. The simulated velocity profile agreed well with that reported previously. The current findings are helpful in the clinical investigations of various arterial diseases.
