Abstract

Different studies have been conducted for radio wave propagation in troposphere using different numerical modelling approaches. The most reliable approach is based on parabolic wave equation (PWE). The modelling of PWE is approached using different numerical schemes that include Split-step Fourier Transform Method (SSFM), Finite Element/Difference method and Wavelet based numerical method. The conventional Finite Element/Difference method are less accurate and/or computationally more expensive. While in comparison, split-step wavelet method (SSWM) is highly accurate and computationally very efficient. The SSWM has been previously used for modelling of PWE with smooth terrain. However, the real conditions are completely different as they contain variable terrain. The irregularities in surface of terrain have considerable influence because of reflection and diffraction on radio-wave propagation. In order to develop an effective communication system, a model that properly incorporates the reflection parameters from the variable terrain. In this research work, the SSWM is proposed for modelling of PWE for radio wave propagation over variable terrain. In SSWM, compactly supported wavelet of Daubechies 6 are used as bases. Obtained results accurately accounts the reflection from rough terrain surface and shows good agreement with SSFM.

Keywords: Communication, Split-step wavelets, numerical, wireless, evaporation duct.

1. Introduction

Band of frequencies in EM spectrum used for wireless communication starts from 9 KHz to 275 GHz. The frequency of wave less than 9 KHz are not used because of limited bandwidth and large antennas size. Similarly, the frequency of wave for more than 275 GHz are not used because of very high attenuation. The propagation of radio wave in any medium is characterized in terms of parameters such as frequency, wavelength, electric field strength (E), magnetic field strength (H), electric polarization, velocity of propagation (v), refractive index and Poynting vector [3], [4]. In order to analyze the properties of an antenna, an isotropic antenna is required. Ideally, the radiation of radio waves with isotropic antenna propagates in all directions. Let the power radiated by an isotropic antenna indicates by \( P_t \), and received power \( P_r \) after covering a distance \( d \) can be obtained as [5],

\[
P_r = \frac{P_t}{4\pi d^2} = \frac{E_0^2}{2\eta_0}
\]  

(1)

where \( P_t \) is transmitted power in Watt, \( E_0 \) is magnitude of electric field in V/m, \( d \) is distance from the transmitter antenna in meter and \( \eta_0 = 120\pi \) is free space intrinsic impedance. The received power can be expressed as,

\[
P_r = \frac{P_t \times G_t \times \lambda^2}{4\pi d^2} = \frac{G_t \times P_t \times G_r \times \lambda^2}{(4\pi d)^2}
\]  

(2)

Where \( G_t \) and \( G_r \) are the transmitter and receiver antenna Gain respectively, \( \lambda = cf \) is wavelength and \( c \) is the speed of light. Equation that is required to compute free space loss \( L_0 \) can be expressed as,

\[
L_0 = 20\log \frac{4\pi d}{\lambda}
\]  

(3)

Substituting \( c = 3\times10^8 \text{ m/sec} \) into Eq. (3) to obtain the expression for \( L_0 \) in terms of decibel as [6], [7],

\[
P_r (\text{dBW}) = P_t (\text{dBW}) - L_0 (\text{dB}) + G_t (\text{dBi}) + G_r (\text{dBi})
\]  

(4)

where \( P_t \) is transmitter output power in dBW (decibel watt), \( L_0 \) is free space loss in decibel dB, \( G_t \) is transmitting antenna gain in dB (decibel of isotropic radiator), \( G_r \) is receive antenna gain in dBi [6], [7]. Molecular constituents in air determines the radio refractive index that is indicated by \( n \). Numerically, there is a very small difference compared to unity. Subsequently, to suitably magnify \( n \) a modified refractivity index, \( N \) is introduced as [8],

\[
N = 3.73 \times 10^6 \frac{e_{wa}}{T_0} + 77.6 \frac{P}{T_0}
\]  

(5)

where atmospheric pressure and atmospheric temperature are indicated by \( P \) measured in mPa and indicate by \( T \) measured in Kelvin respectively. Similarly, \( e_{wa} \) is water vapor pressure (in mbar).

The refractivity index decreases linearly as 40 N-unit per kilometer. Radius of curvature of radio wave path at low elevation angle is [8], [9].

\[
\frac{1}{\rho} = \frac{dn}{dz}
\]  

(6)  

where \( \rho \) and \( n \) are radius of earth curvature and refractive index of the atmosphere respectively. Similarly, \( \frac{dn}{dz} \) is vertical gradient of refractive index. Effective Earth radius \( R_e \) can be given as,

\[
\frac{1}{R_e} = \frac{1}{K_{geo}} = \frac{1}{a_e} + \frac{dn}{dz}
\]  

(7)  

In Eq. (7), \( a_e = 6375 \) Km is Earth radius, \( K_{geo} \) is coefficient of terrestrial radius. Let assume the earth is a flat plane to modify the earth curvature. Subsequently the modified refractivity can be expressed as [1],

\[
M = N + \left( \frac{z}{6375 \text{Km}} \right) \times 10^6 = N + 157z
\]  

(8)  

Using Eq. (8) for gradient of modified refractivity index as,

\[
\frac{\partial M}{\partial z} = \frac{\partial N}{\partial z} + 157
\]  

(9)  

The different refractive conditions have been discussed in literature namely sub-refraction, standard refraction, super reflection and trapping. Ray with different refractive gradient conditions (N-gradient and M-gradient) are discussed in [5], [10]. The trapping conditions of radio wave propagation creates reflection, refraction and diffraction. The most reported tropospheric ducts are ground based ducts, surface-based duct, elevated duct and evaporation duct as shown in Fig 1. The lower boundary of 1st two ducts are the surface of the Earth. However, in elevated and evaporation duct, both top and bottom boundaries are upside from the earth surface as discussed in [11]. From the aforementioned trapping duct, the surface-based duct, surface duct and elevated duct occurs for very short time [12].

2. RADIO wave Propagation

Basic theory of time varying electromagnetic field is driven from Maxwell’s equations. To analyse each component of propagated radio wave, one requires a coordinate system. Subsequently, we consider spherical coordinate system \((r, \theta, \phi)\) as discussed in [4]. Let consider the earth centre and source is positioned along \( z \)-axis. Hence Maxwell’s equations can be expressed as [13], [15],

\[
\nabla \times E = jk_n Z_o H,
\]  

(10)  

\[
Z_o \nabla \times H = -jk_n jn^2 E,
\]  

(11)  

\[
\nabla \cdot E = 0,
\]  

(12)  

\[
\nabla \cdot H = 0.
\]  

(13)  

where \( n \) is refractivity index of atmosphere, \( Z_o = 120\pi \Omega \) is impedance of vacuum, \( j \) is imaginary constant and \( k_o = 2\pi/\lambda \) is the wave number, where \( \lambda \) is the wavelength. In order to obtain the governing field equation for vertical propagation and horizontal propagation, following assumption are made. Let the EM field components \((E_r, E_\theta, H_\phi)\) be zero for horizontal polarization and resultant equation can be expressed as [15],

\[
\frac{\partial^2 \psi_r}{\partial r^2} + \frac{1}{r} \frac{\partial \psi_r}{\partial r} + \frac{1}{r^2} \frac{\partial^2 \psi_r}{\partial \theta^2} + \left( k_o^2 n^2 - \frac{3}{4r^2 \sin \theta} \right) \psi_r = 0.
\]  

Similarly, the governing field equation for vertical polarization is as [14],

\[
\frac{\partial^2 \psi_\theta}{\partial r^2} + \frac{1}{r} \frac{\partial \psi_\theta}{\partial r} + \frac{1}{r^2} \frac{\partial^2 \psi_\theta}{\partial \theta^2} + \left( k_o^2 n^2 + \kappa \right) \psi_\theta = 0,
\]  

where in Eq. (16), \( \kappa \) can be computed as [15],

\[
\kappa = k_o^2 n^2 + \frac{3}{4r^2 \sin \theta} - \frac{2}{n^2 r^2} \left( \frac{\partial^2}{\partial r} \right)^2 \psi_r + \frac{1}{n^2 r^2} \frac{\partial^2}{\partial \theta} - \frac{1}{n^2 \sin \theta} \frac{\partial}{\partial \theta} - \frac{2}{n^2} \left( \frac{\partial}{\partial \theta} \right)^2 \psi_r.
\]  

In Eq. (17), terms \([-2/n^2 \left( \partial^2 \psi_r/\partial \theta \right)^2 + (1/n) \left( \partial^2 \psi_r/\partial r \right) \] can be modified as in [15] and expressed as,

\[
-2/n^2 \left( \partial^2 \psi_r/\partial \theta \right)^2 + \frac{1}{n^2 r^2} \frac{\partial^2}{\partial r} \left( \frac{\partial \ln n}{\partial r} \right)^2.
\]  

(15)  

Subsequently Eq. (17) can be rewritten as,

\[
\kappa = k_o^2 n^2 + \frac{3}{4r^2 \sin \theta} + \frac{\partial^2 \ln n}{\partial r^2} \left( \frac{\partial \ln n}{\partial r} \right)^2 + \frac{1}{n^2 r^2} \frac{\partial^2}{\partial \theta} - \frac{1}{n^2 \sin \theta} \frac{\partial}{\partial \theta} - \frac{2}{n^2} \left( \frac{\partial}{\partial \theta} \right)^2 \psi_r.
\]  

(16)  

Let assume a stratified atmosphere where \( n \) is the function of height then,
\[ \frac{\partial u}{\partial \theta} = 0, \quad \frac{\partial^2 n}{\partial \theta^2} = 0. \]

Then Eq. (20) can be modified as,
\[ \kappa = k_0 n^2 + \frac{3}{4 r^2 \sin^2 \theta} - \left( \frac{\partial \log n}{\partial r} \right)^2. \]

where \( \log(n) \) with respect to \( r \) is very small so,
\[ \kappa = k_0 n^2 + \frac{3}{4 r^2 \sin^2 \theta} \]

Eq. (16) can be expressed as,
\[ \frac{\partial^2 \psi}{\partial x^2} + \frac{1}{r} \frac{\partial \psi}{\partial r} + \frac{1}{r^2} \frac{\partial^2 \psi}{\partial \theta^2} + \left( k_0^2 n^2 + \frac{3}{4 r^2 \sin^2 \theta} \right) \psi = 0. \]

Transforming Eq. (16) into \((x, z)\) coordinates to obtain expression for vertical polarized field as,
\[ \frac{\partial^2 \psi}{\partial x^2} + k_0^2 n^2 \psi_{,z} (x, z) = 0, \]

where \( \psi_{,z} = (k_0 \sin \theta / n) H_0 \) Eq. (15) and (16) are the 2D scalar EM wave equations for propagation of horizontally and vertically polarized field respectively.

3. Methodology

Split-Step Wavelet Method (SSWM) and Wavelet Galerkin method have relatively same features except for boundary handling [1]. Image theory method based on periodic wavelet function is used to handle the boundary condition in SSWM. Subsequently, geometrical of the problem is modified as shown in Fig. 2. Now the range of actual domain with respect to \( z \) is changed from \( [0, Z_{\text{max}}] \) to \( [-Z_{\text{max}}, Z_{\text{max}}] \). The symmetric extension of both field and absorbing layer can be written as,
\[ u(x, -Z_{\text{max}}) = u(x, Z_{\text{max}}) = 0 \]

![Fig. 2. Extension of solution domain with rough surface using image theory method.](image)

Domain extension satisfies the periodic boundary condition. The periodicity restricts the spatial domain for interval \([-Z_{\text{max}}; Z_{\text{max}}]\). Now using wavelet expansion of function \( u(x, z) \) as,
\[ u(x, z) = \sum_{l=0}^{N-1} a_l(x) \rho(z-l); \quad z \in [-Z_{\text{max}}, Z_{\text{max}}] \]  

where \( a_l(x) \) are coefficients which are needed to compute \( \rho(z) \) are the scaling function. By adopting a procedure that is similar to the Wavelet Galerkin Method to obtain equivalent numerical expression as,
\[ \int_{Z_{\text{min}}}^{Z_{\text{max}}} \left( a_{l}(u(x)) + 2 j k_0 \frac{d}{dx} + k_0 (m^2 - 1) u \right) dz = 0. \quad (27) \]

Substitution of Eq. (26) into Eq. (27) as,
\[ \sum_l \int_{Z_{\text{min}}}^{Z_{\text{max}}} a_{l}(u(x)) x \phi dz + \sum_l \int_{Z_{\text{min}}}^{Z_{\text{max}}} \frac{j}{2 k_0} \frac{d}{dx} \phi dz \]

\[ + \sum_l \int_{Z_{\text{min}}}^{Z_{\text{max}}} \frac{j k_0}{2} \int (m^2 - 1) \phi dz = 0 \quad (22) \]

The matrix notation of Eq. (28) can be expressed as
\[ [I_{k,l}]/[\hat{\psi}(a_l(x))] + [L_{k,l} + S_{k,l}][a_l(x)] = 0 \]

where,
\[ I_{k,l} = \delta_{k,l} \int_{Z_{\text{min}}}^{Z_{\text{max}}} \phi dz , \]
\[ L_{k,l} = -\frac{j}{2 k_0} \int_{Z_{\text{min}}}^{Z_{\text{max}}} \frac{d}{dx} \phi dz , \]
\[ S_{k,l} = -\frac{j k_0}{2} \int_{Z_{\text{min}}}^{Z_{\text{max}}} (m^2 - 1) \phi dz , \]

In above equations, \( \delta_{k,l} \) is the Kronecker delta function and \( \Gamma^{0,2} \) are known as connection coefficient as discussed in [17]. Now using the modifiable refractivity constant on an element then \( S_{k,l} \) can be expressed as [19].
\[ S_{k,l} = -\frac{j k_0}{2} (m^2 - 1) \phi dz, \]

Eq. (27) is an initial value problem. The split-step method derives from the fact that the solution of problem Eq. (27) satisfies the identity
\[ \{a_l(x + \Delta x)\} = \exp(L + S) \Delta x \{a_l(x)\} \]

The exponential operator given in Eq. (31) can be split in two different ways as,
\[ \{a_l(x + \Delta x)\} = \exp(L \Delta x) \exp(S \Delta x) \{a_l(x)\} \]

and
\[ \{a_l(x + \Delta x)\} = \exp(L \frac{\Delta x}{2}) \exp(S \frac{\Delta x}{2}) \exp(L \frac{\Delta x}{2}) \{a_l(x)\} \]

where the form in Eq. (32) in known as asymmetrical splitting and the other form given in Eq. (33) in called symmetric splitting. It has been discussed in [20] as asymmetrical splitting is accurate to the order \( O(\Delta x^2) \), while form of symmetric splitting is accurate to the order \( O(\Delta x^3) \). In Eq. (29), \( S_{k,l} \) is a diagonal matrix, the exponential of \( S_{k,l} \) is required in Eq. (31) that can be solved with less computational time. However, \( S_{k,l} \) is a circulant matrix, subsequently its need to compute the exponential of operator \( S_{k,l} \). Let,
\[ P = e^P; \quad Q = L^\nu / 2 \]

Using the fact that \( S_{k,l} \) is circulant, one can compute Eq. (30) by using Fast Fourier Transform (FFT) as discussed in [18],
\[ P = -\exp \{ L \} \]

where \( L_q = \text{diag}(q) \), \( q = Fq \) and \( q \) is first column in \( Q \) matrix, and \( F \) is FFT.
4. Numerical Implementation of SSWM

In order to obtain the solution of Eq. (16) with proposed method, the computational domain is assumed to be periodic for an interval of \([Z_{\text{max}}, Z_{\text{max}}]\). The matrices of Eq. (28) needs to be properly scaled as defined in physical space. Detailed procedure for scaling the solution matrix is provided in [18]. Assuming the solution domain is classified in to \(N_l\) number of grids points then the indices \(l = k = 0, \ldots, N_a - 1\) and the dimensions of resultant obtained linear system of Eq. (28) will be \(N_a \times N_a\). The organization of solution matrix provided in Eq. (28) gives the following structure where length of compactly supported Daubechies wavelet is 6.

\[
I_{kj} = \frac{1}{(2Z_{\text{max}})^2} \begin{bmatrix}
I_{0,0} & I_{0,1} & \cdots & I_{0,N_a-1} \\
I_{1,0} & I_{1,1} & \cdots & I_{1,N_a-1} \\
\vdots & \vdots & \ddots & \vdots \\
I_{N_a-1,0} & I_{N_a-1,1} & \cdots & I_{N_a-1,N_a-1}
\end{bmatrix}
\]

\[
S_{kj} = \text{diag} \left[ S_{0,0}, \ldots, S_{N_a-1,0} \right]
\]

\[
I_{kj} = [F]_{N_a \times N_a}^T
\]

and \(a_i(z) = [a_0, \ldots, a_{N_a-1}]^T\).

A symmetric extension of refractive profile is taken in extended domain as shown in Figure 2 and we can write,

\[
S_{kj} = S_{kj}; \quad k,l = (0,\ldots,N_a-1); \quad \hat{k},\hat{l} = (\hat{0},\ldots,\hat{N_a}-1)
\]

Initital field is computed at \(x = 0\) and in order to satisfy the BCs over perfectly conducting surfaces in SSWM, the unknown coefficients \(\bar{a}_i(x)\) are computed for Dirichlet and Neumann BCs as shown in Fig. 2. In order to reduce computational time, the sine and cosine transforms are used for Dirichlet and Neumann BCs, respectively. Since, Split-Step wavelet transform is inspired from Split-step Fourier transform.

In order to radiate radio waves through troposphere under evaporation duct phenomenon, the propagation losses are computed at frequency of 3.8 GHz and 7.8 GHz because of prominent trapping conditions in such range. In simulation, rough terrain type is obtained through MATLAB function \textit{rand} in which the maximum height of the rough terrain is assume 4 m as illustrated in Fig. 2. The height, polarization and beam-width are assumed 10 m, horizontally and 2\(^\circ\) respectively. Grid sizes along the \(X\)-axis and \(Z\)-axis are 200 m and 0.054 m respectively. The height verses modified refractive index for evaporation duct is provided in Table 1. The solution for field governing equation is obtained through SSWM and SSFM for comparison. The parameters used in this simulation are summarized in Table II.

The propagation of radio waves over variable terrain includes vertically open region. In order to truncate the domain vertically along \(Z\)-axis, the absorbing boundary conditions are used for yielding non-physical reflection from the top boundary. It is achieved by using window called hamming window. The bottom boundary is assumed to be perfectly electrical conducting earth surface.
